1 **Abstract:**

2 Background:

3 The COVID-19 toll of cases and deaths followed an uneven pattern across the world. The literature has
4 partly explained the observed discrepancy between the different countries by country-specific and
5 systemic patterns worldwide. In this study, we propose an additional explanation that the magnitude of
6 COVID-19 toll reported to the WHO could be influenced by the level of free speech and Democracy in
7 the reporting countries.

8 Methods:

9 We constructed a longitudinal dataset including the daily COVID-19 count of cases and deaths
10 worldwide and each country's respective score on the Freedom in the World index. We applied two
11 Generalized Estimating Equation models to investigate if a country's reported toll count of COVID-19
12 cases and deaths is related to that country's freedom level. We controlled for factors identified in the
13 current literature to affect the pandemic's spread.

14 Results:

15 A country's score on the Freedom In the World Index was associated with its reported COVID-19 cases
16 count (57028.43, 95% CI 985.3619 - 113071.5, P= 0.0461) and deaths count (3473.273, 95%
17 CI1217.12-5729.42, P=.002). Also, despite having almost equal shares of the world's population,
18 countries at the bottom category of the Freedom index reported 21% and 11% of the COVID-19 toll
19 cases and death counts reported by countries of highest scores on the index, respectively.

20 Conclusions:

21 The known magnitude of the COVID-19 pandemic's morbidity and mortality appears to be as
22 transparent as the reporting countries uphold free speech and Democracy. This pattern could
23 potentially misguide international aid and global vaccine distribution plans.

24

25 **Introduction:**

26 Concurrent to the news on COVID-19 vaccines, the question has arisen on the order of priority in
27 distributing them. On the national level in the United States, the CDC was prompt to establish
28 broad vaccine distribution phases.¹ On the international level, the debate is escalating on balance
29 between some countries' financial ability to secure their vaccine supplies and the needs of mid
30 and low-income countries.² A critical, yet not fully verified, assumption basing many of the
31 involved public health and logistic considerations is that the information we have on the COVID19
32 global spread is independent and transparent enough to be an accurate representation of its real
33 impact. In this research, we examined the validity of this assumption on the global level.

34 Since the beginning of the epidemic, multiple factors cast doubt on the COVID-19 toll calculations'
35 accuracy in different countries. There was a lack of consistency in selecting high-risk population
36 groups that some countries initially monitored for COVID-19.³ Government authorities
37 worldwide used various combinations of clinical, epidemiological, and laboratory confirmation
38 requirements to determine which cases constitute COVID-19 cases as the primary ailment.⁴ The
39 types, availability, and accuracy of the testing kits used in screening for COVID-19 varied
40 worldwide at different time points. Eventually, most countries used various diagnostic tools of
41 different sensitivities though not all countries could always have enough testing kits.
42 Manufacturing limitations sometimes added to the uncertainty on some of the available kits.⁵

43 Despite these considerable differences between the individual countries, there have been
44 observable systematic patterns in the COVID-19 impact numbers on the national and
45 international levels, revealing socio-economic challenges for minorities and disadvantaged
46 populations. For example, in the US, minority populations were disproportionately impacted by
47 the COVID-19 epidemic, prompting questions on the health equity considerations and barriers to
48 care.⁶ At the global level, other systemic patterns appeared in the COVID-19 toll of cases and
49 deaths, such as the seemingly paradoxical observation that the epidemic could be spreading at
50 higher rates in developed and prosperous countries than others of weaker health care
51 infrastructure.⁷

52 Another observation, which the current literature has not fully explained yet, is the discrepancy
53 between countries in their counts of COVID-19 cases and deaths.⁸ The full explanation of this
54 observation could reveal what makes a country more vulnerable to COVID-19 and which
55 countries are the hotspots of the epidemic and logistic priorities in vaccine distribution.⁹ The
56 literature has proposed factors of weather, location, health care infrastructure, aging population,
57 and others. These explanations could only partly decipher the epidemic's spread pattern.¹⁰ In
58 this study, we proposed an additional explanation that identifies a potential barrier to equitable
59 channeling of support, including vaccines, to genuine need populations. Our research hypothesis
60 is that the magnitude of a country's reported toll of COVID-19 cases and deaths could be under
61 the influence of the degrees of Freedom of speech and Democracy that country embraces. The
62 less a government upholds these governance elements, the lower impact it could be reporting
63 about the epidemic in its people. The premises of this hypothesis are the inconsistent spread of
64 COVID-19 across the globe without a full explanation, multiple media reports on governments
65 considering independent reporting on COVID-19 as misinformation, and studies from
66 independent research institutions highlighting a step up in governmental control and a decline in
67 Democracy in around the world during the pandemic.^{11,12,13,14}

68 On top of misguiding scientific efforts, this possibility would likely create a barrier to equitable
69 access to the COVID-19 vaccines. The perceived low impact of the epidemic in some countries
70 could mislead the distribution efforts championed by the international organizations and the
71 vaccine manufacturers into deprioritizing sending vaccine aid to these populations, contrary to
72 their actual need.

73 To investigate this hypothesis, we conducted this longitudinal analysis of the potential
74 relationship between the toll of cases and deaths reported by the world countries and their
75 respective scores on the Freedom In the World Index, recognized in the politico-economic
76 literature as a measure of Democracy and Free speech around the globe.

77 **Study Data And Methods:**

78 The observation unit was daily country. We collected records of confirmed COVID-19 impact
79 reported to the WHO from world countries. Our study dataset tracked 182 countries over 242
80 days from January 23, 2020, to September 20, 2020.

81 Outcome of Interest:

82 We examined the cumulative daily counts of confirmed COVID-19 cases and deaths from the
83 COVID-19 dashboard provided by the Center for Systems Science and Engineering (CSSE) at Johns
84 Hopkins University. This online repository hosts data on COVID-19 deaths and cases worldwide,
85 collected from official and independent sources.

86 Predictor variable:

87 We used Freedom In the World Index (2020) to represent Democracy and Free speech in the
88 world countries¹³. This annual index is developed by the US-based independent research
89 institution Freedom House (US). The index is a composite score on a scale from one to a hundred,
90 aggregating each country's sub-scores on a wide array of surveyed measures of Democracy such
91 as political pluralism, Freedom of expression, the rule of law, and individual rights. Each country
92 is also designated a Freedom In the World status (Free, Partly Free, or Not Free) based on its
93 respective aggregate scores on Political Rights and Civil Liberties.¹⁵

94 Covariates:

95 We added control variables representing the different factors hypothesized in the current
96 literature to influence the spread of COVID-19. The model included fixed effects for daily
97 temperature and ultraviolet index levels, sourced from WeatherStack data repository, which
98 collects worldwide weather data from stations worldwide.¹⁶ Additionally, we added fixed effects
99 of worldwide enactment of containment measures and public health policies, represented by
100 daily records in Government Stringency Index developed by Oxford University s.¹⁷

101 We also added fixed effects for pollution levels (in mean annual exposure in micrograms per cubic
102 meter, 2017),¹⁸ population density (2019), and wealth (in the 2019 gross domestic product in
103 PPP). We obtained this information from the World Bank Databank. Finally, we used the Health

104 Access and Quality Index (2016), which scores the accessibility of health care services in the
105 different countries, as a proxy of the accessibility to care during the COVID-19 epidemic.

106 Methods:

107 We estimated the relationship between the countries' scores on the Freedom In the World index
108 and their reported cumulative count of COVID-19 cases and deaths, using a Generalized
109 Estimating Equation (GEE) model with an independent correlation structure. The model included
110 the aforementioned covariates believed, in the consensus of literature in multiple scientific
111 disciplines, to influence the global spread of COVID-19. We used SAS 9.4 TS Level 1 M6 to conduct
112 the statistical analysis and impute the missing data. Although multiple imputations is not a
113 required step for GEE models, for being population-based models, the consensus in Biostatistics
114 literature is that imputing the missing data improves the adequacy of the GEE parameter
115 estimates.

116 Results:

117 Descriptive statistics:

118 In the Free category, the highest scores on the Freedom In the World Index, there are 72
119 countries. This category collectively hosts 38.28% of the world population and reported 72.37%
120 of the world's COVID-19 caseload and 78.77% of the world's COVID-19 related deaths. Countries
121 in this category produced 56.56% of the world's 2019 GDP in PPP and had an average score of
122 76.94 on the Health Access and Quality index. (Figure 1)

123 In the Not Free category, the lowest scores category, there are 48 countries. They collectively
124 host 36.3% of the world population and accounted for 15% of the total world COVID-19 cases
125 and 8.7% of the total deaths. These countries produced 29.66% of the world GDP in PPP and had
126 an average score of 51.81 on the Health Access and Quality index. (Figure 1)

127 Inferential statistics:

128 There was a statistically significant positive association between a country's score on the
129 Freedom In the World Index and the cumulative count of cases that the government reported.

130 For every point decrease on the index, the average country reported 57028 less cumulative
131 COVID-19 cases, and vice versa (57028.43, 95% CI 985.3619 - 113071.5, P= 0.0461). There was
132 also a statistically significant positive association between a country's score on the index and the
133 cumulative count of deaths it reported. For every point decrease on the index, the respective
134 country reported 3473.27 less COVID-19 deaths, cumulative, over the study period (3473.273, 95%
135 CI1217.12-5729.42, P=.002). (Figure 2)

136 Discussion:

137 The results suggest a relationship between the COVID-19 toll reported to the World Health
138 Organization from the different countries and the respective countries' levels of Freedom. The
139 less a country embraced Democracy and Free speech, the lower the magnitude of the COVID-19
140 morbidity and mortality it reported to the world about its people. Countries in the Not Free
141 category reported shares of global COVID-19 cases and deaths were 21% and 11% of the counts
142 reported by the Free category, respectively, despite that the two categories have almost equal
143 shares of the world population. Paradoxically, the Not Free category had poorer economy and
144 weaker health care infrastructure, in terms of access and quality, than the Free category. This
145 discrepancy is independent of the factors believed to influence the pandemic's spread, such as
146 access to health care, containment measures and public health policies, weather conditions,
147 pollution, demographic characteristics, or wealth.

148 These findings cast doubt on the validity of the assumption that the observed toll of COVID-19
149 morbidity and mortality counts is transparent enough to represent the reality of the epidemic's
150 impact accurately. Without a valid representation of the COVID-19 reality, scientific efforts could
151 investigate inaccurate findings and drive unreliable conclusions, leading to a misallocation of
152 global aid resources.

153 For example, the currently available information led some research efforts to investigate a
154 perceived observation that the pandemic has not affected low-income countries as it did with
155 high-income countries. One explanation was that rich countries could afford broader screening
156 efforts, which will ultimately detect a higher number of cases than other countries. Yet, this

157 study's findings could propose an entirely different explanation considering that many low-
158 income countries also have low embracement of Democracy.

159 Another example is the apparent association between colder temperatures and the spread of the
160 virus, which led some to believe that the summer would restrain the epidemic early in the
161 epidemic's timeline.¹⁹ Some researchers suggest that this misperception probably deterred the
162 COVID-19 response in the summer of 2020 by encouraging complacency in following social
163 distancing measures, at least in part.²⁰ Yet, in the light of the findings in this study, we could
164 consider the possibility that the low COVID-19 impact in hot countries in areas like Africa could
165 be partially coming from a lack of Freedom of speech and low Democracy.

166 In future consideration, the perceived impact of the epidemic could be a key element in allocating
167 international aid and vaccine quotas to developing countries. Considering the findings, the
168 international organizations and vaccine manufacturers will likely deprioritize aid to some
169 countries based on their low toll of COVID-19 cases and deaths, which could be, at least in part,
170 because of a lack of transparency in reporting the reality of the COVID-19 situation in them. This
171 role of lack of Democracy as a barrier against access to care could be a new socio-economic
172 determinant of health care in the COVID-19 epidemic. Further research could help bridge this
173 barrier by considering various cultural and socio-economic factors that could influence a
174 country's government ability and willingness to help the international community get a realistic
175 understanding of the epidemic. While such scientific inquiry goes beyond this study's scope, this
176 study's findings could be a useful starting point for decision-makers and members of the research
177 community working to promote equitable access to the global pool of therapeutic and preventive
178 aid resources.

179 Limitations:

180 This study has several limitations. First, the inconsistencies between the standards that different
181 countries have followed to varying points of time in the study period could introduce inaccuracies
182 in the COVID-19 toll count of cases and deaths used in the analysis. Second, we did not obtain
183 information on the availability of COVID-19 testing in different countries, which might shape the
184 observed spread pattern. Third, the weather information used in the analysis is on each country's

185 political capital, which might not be fully representative of the weather in all that country's
186 regions. Fourth, the study's analysis does not divulge the causality considerations underlying the
187 findings, which could be an area for further research.

188 Declaration of Conflicting Interests:

189 The authors declared no potential conflicts of interest with respect to the research, authorship,
190 and/or publication of this article.
