Abstract

Background: Herpes simplex virus type 2 (HSV-2) infection is a prevalent sexually transmitted infection with a sizable disease burden that is highest in sub-Saharan Africa. This study aimed to characterize HSV-2 epidemiology in this region.

Methods: Cochrane and PRISMA guidelines were followed to systematically review, synthesize, and report HSV-2 related findings. Meta-analyses and meta-regressions were conducted.

Findings: From 218 relevant publications, 451 overall outcome measures and 869 stratified measures were extracted. Pooled incidence rates ranged between 2.4-19.4 per 100 person-years across populations. Pooled seroprevalence was lowest at 37.3% (95% confidence interval (CI): 34.9-39.7%) in general populations and high in female sex workers and HIV positive individuals at 62.5% (95% CI: 54.8-70.0%) and 71.3% (95% CI: 66.5-75.9%), respectively. In general populations, pooled seroprevalence increased steadily with age. Compared to women, men had a lower seroprevalence with an adjusted risk ratio (ARR) of 0.61 (95% CI: 0.56-0.67). Seroprevalence decreased in recent decades with an ARR of 0.98 (95% CI: 0.97-0.99) per year. Seroprevalence was highest in Eastern and Southern Africa. Pooled HSV-2 proportion in genital ulcer disease was 50.7% (95% CI: 44.7-56.8%) and in genital herpes it was 97.3% (95% CI: 84.4-100%).

Interpretation: Seroprevalence is declining by 2% per year, but a third of the population is infected. Age and geography play profound roles in HSV-2 epidemiology. Temporal declines and geographic distribution of HSV-2 seroprevalence mirror that of HIV prevalence, suggesting sexual risk behavior has been declining for three decades. HSV-2 is the etiological cause of half of GUD and nearly all genital herpes cases.

Funding: This work was supported by pilot funding from the Biomedical Research Program at Weill Cornell Medicine in Qatar and by the Qatar National Research Fund [NPRP 9-040-3-008].

Introduction

Herpes simplex virus type 2 (HSV-2) infection is a highly prevalent sexually transmitted infection (STI) worldwide.(1) It is a leading cause of genital ulcer disease (GUD) and genital herpes, manifesting in the form of painful, recurrent, and frequent genital lesions.(2-8) Its vertical transmission from mother-to-child can lead to neonatal herpes, a severe and sometimes fatal outcome in newborns.(3, 9) HSV-2 is linked to a 3-fold increase in sexual transmission and acquisition of HIV,(10-12) implying a potential epidemiological synergy between the two viruses.(11, 13, 14)

HSV-2 is typically asymptomatic in most of those who acquire it.(3) This trait coupled with HSV-2's chronic and reactivating nature, as well as its subclinical shedding,(15, 16) increases its rate of transmission and leads to high antibody prevalence (seroprevalence) among general and higher-risk populations alike.(11, 17, 18) Since HSV-2 is more transmissible than HIV and produces long-lasting antibodies, it has been used as an objective biological marker of sexual risk behavior and risk of HIV infection.(19-23) Analyses using empirical data and mathematical modeling supported the utility of using HSV-2 seroprevalence to predict HIV epidemic potential.(19, 20, 24)

Inadequate understating of HSV-2 epidemiology and its considerable consequences on sexual and reproductive health and the HIV epidemic,(11, 13) calls for urgent preventive and control measures to tackle it. The World Health Organization (WHO) outlined a “Global Health Sector Strategy on STIs”(25) that sets goals to eliminate STIs as a main public health concern by 2030 through integration of preventive and control measures. Consequently, WHO, along with their global partners, are spearheading efforts to develop an HSV vaccine as an urgent priority.(26, 27)

To inform these efforts, we conducted a systematic review to characterize HSV-2 infection levels and trends in sub-Saharan Africa (SSA), the hub of the HIV epidemic.(28, 29) We estimated pooled means for each outcome measure (incidence rate, seroprevalence, proportion of HSV-2 in GUD, and proportion of HSV-2 in genital herpes) across populations and subpopulations. We also conducted meta-regression analyses to assess temporal trends and identify predictors of high seroprevalence and between-study heterogeneity.

Methodology

Data sources and search strategy

This systematic review was guided by the Cochrane Collaboration Handbook(30) and was reported according to the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines(31) which can be found in Table S1. The review was informed by the methodology applied recently in a series of systematic reviews for HSV-1 infection.(32-36)

All available publications were systematically reviewed up to August 23, 2020. The search was conducted in PubMed and Embase databases, using search strategies with exploded MeSH/Emtree terms, broad search criteria, and no language or year restrictions to widen the scope and include all subheadings (Table S2). The definition of Africa included 45 countries, as defined by the WHO for the African Region,(37) covering countries of sub-Saharan Africa. The list of countries and their subregional stratification is in Box S1.

Study selection and eligibility criteria

Search results were imported into the reference manager Endnote (Thomson Reuters, USA), whereby duplicate publications were identified and removed. The remaining records were

screened for relevance based on titles and abstracts, followed by full text screening of relevant and potentially relevant records. Additional bibliography screening was performed on both reviews and the relevant articles to identify any missing publications.

Inclusion criteria were met if publications reported primary data on any of the following four outcomes: 1) HSV-2 incidence rate, 2) HSV-2 seroprevalence, 3) proportion of HSV-2 detection in GUD, and 4) proportion of HSV-2 detection in genital herpes. A sample size of ≥ 10 was required for inclusion for all outcome measures. Exclusion criteria encompassed case reports, series, commentaries, reviews, and qualitative studies. In this review, “publication” refers to a document reporting any outcome measure, whilst a “study” refers to details of a specific outcome measure. Special care was given to ensure that overlapping studies were only included once and not in duplicate.

Data extraction and synthesis

Data extraction and double extraction were performed by MH and FA independently. A list of extracted variables is in Box S2.

Overall outcome measures and their stratified measures were extracted, provided the stratification agreed with a pre-set stratification hierarchy and the subsample in each stratum was ≥ 10 . The pre-set stratification hierarchy sequence for incidence and seroprevalence measures was as follows: population type (see Box S3 for definition), sex, and age. As for proportion of HSV-2 detection in GUD and genital herpes, the sequence was: genital herpes episode status (primary *versus* recurrent episode), sex, age, and study site (hospital *versus* outpatient clinic).

Measures reporting any HSV-2 outcome among children <15 years old were only reported, and not included in the analyses.

Quality assessment

Relevant studies were subjected to a pre-quality assessment to evaluate the validity of the assays used, given their limitations.(38, 39) This assessment was done with the help of an expert from the University of Washington, Professor Rhoda Ashley-Morrow. Only studies with valid, sensitive, and specific assays were included in the review. These studies were then evaluated using the Cochrane approach for risk of bias (ROB) assessment.(30) Study's precision was classified into low *versus* high based on the study sample size (<100 *versus* \geq 100).(40) Studies were classified into low *versus* high ROB using two quality domains: sampling method (probability *versus* non-probability based sampling) and response rate (\geq 80% *versus* <80% or unclear). Effect of ROB on study outcome was investigated through meta-regression as noted below.

Meta-analyses

Pooled mean estimates for all four outcomes were calculated across all strata using meta-analyses, provided each stratum had \geq 3 measures.

Only studies reporting incidence rate by person-time were included in the meta-analyses. Log transformed incidence rates were used to calculate pooled estimates using the inverse variance method in the metarate function.(41, 42)

HSV-2 seroprevalence measures and proportion of HSV-2 detection in GUD and in genital herpes were each pooled using the DerSimonian-Laird random-effects model,(41) applying the Freeman-Tukey double arcsine transformation to stabilize the variance,(43) and factoring knowledge of the applicability of this transformation.(44)

Existence of heterogeneity in effect size was assessed using Cochran's Q statistic.(41, 45)

Magnitude of between-study variation attributed to *true* difference in effect size, as opposed to *chance*, was measured using I^2 .(41, 45) Distribution of *true* measures around the pooled mean was described using the prediction interval.

Meta-analyses were conducted in R version 3.4.1(46) using the meta package.(42)

Meta-regressions

Univariable and multivariable random-effects meta-regression analyses were conducted using log transformed seroprevalence measures to examine factors and predictors potentially associated with increased HSV-2 seroprevalence, as well as sources of between-study heterogeneity. Pre-set variables included in these analyses are listed in Box S4.

Factors included in the multivariable models had to have a p-value<0.1 in the univariable model. Strength of evidence for an association was deemed significant for factors with a p-value<0.05 in the multivariable models.

Meta-regressions were conducted in Stata/SE version 13(47) using the metareg package.(48)

Role of the funding source

The funder of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the article. The corresponding author had full access to all the data in the study and had the final responsibility for the decision to submit for publication.

Results

Search results and scope of evidence

Figure 1 depicts the PRISMA flow chart describing the study selection process.(31) A total of 14,830 citations were captured in the initial search (2,039 from PubMed and 12,791 from Embase). After deduplication, title and abstract screening, and full text screening, relevant publications were identified. Thirteen additional publications, including country level reports, were identified through bibliography screening.(49-61)

In total, 218 publications met the inclusion criteria. Extracted measures encompassed 47 seroconversion rates, 48 overall (65 stratified) incidence rates, 322 overall (773 stratified) seroprevalence measures, 25 overall (31 stratified) proportions of HSV-2 detection in GUD, and 9 overall (11 stratified) proportions of HSV-2 detection in genital herpes.

Incidence overview and pooled mean estimates for HSV-2 incidence rate

Table S3 summarizes extracted seroconversion and incidence rates. Studies were either longitudinal cohorts (number of measures (n)=35; 49.2%) or randomized controlled trials (n=36; 50.7%), with a follow-up duration ranging between 6 weeks to 6 years. HSV-2 seroconversion rates (n=47) ranged between 0.0-58.0% across studies, reflecting in part the widely variable duration of follow-up.

In general populations, HSV-2 incidence rates among women (n=20) ranged between 3.6-21.7 per 100 person-years with a median of 7.5 and a pooled mean of 7.2 (95% confidence interval (CI): 5.5-9.4) per 100 person-years (Table 1). Among men (n=20), incidence rate ranged between 1.5-10.5 per 100 person-years with a median of 5.5 and a pooled mean of 4.1 (95% CI: 3.1-5.3) per 100 person-years. Higher incidence rates were found in higher risk populations. A summary of pooled mean incidence rate by population type and associated forest plots are in Table 1 and Figure S1, respectively.

Prevalence overview

Tables S4, S5, S6, S7, and S8 summarize (the overall) seroprevalence measures (n=322) across the subregions of SSA. Half the studies were published after the year 2010 (n=176; 55.5%), and most were based on cross-sectional study design (n=202; 62.7%) and convenience sampling (n=233; 72.4%).

For the stratified seroprevalence measures, HSV-2 seroprevalence among general population women (n=290) ranged between 0.1-97.4% with a median of 43.1%, and among general population men (n=186) between 0.0-84.2% with a median of 27.5% (Table 2).

In higher-risk populations (n=40), almost all studies were conducted among female sex workers (FSWs; n=39) with seroprevalence ranging between 4.3-99.0% with a median of 65.0% (Table 2). High seroprevalence was observed in HIV positive individuals and in individuals in HIV discordant couples, ranging between 42.0-95.2% with a median of 79.7% among women (n=20), and between 44.0-94.2% with a median of 61.4% among men (n=15).

Tables 2, 3, and S9 summarize HSV-2 seroprevalence measures for further populations and subpopulations, including by population type, country, subregion, age, sex, and year of publication.

Pooled mean estimates for HSV-2 seroprevalence

Tables 2, 3, and S9 show results of seroprevalence meta-analyses across populations and subpopulations. Pooled mean seroprevalence was lowest at 37.3% (95% CI: 34.9-39.7%) in general populations (n=507), followed by 47.4% (95% CI: 43.2-51.5%) in HIV negative populations (n=51), 57.1% (95% CI: 50.1-63.9%) in intermediate-risk populations (n=45), 61.2% (95% CI: 56.5-65.9%) in STI clinic attendees and symptomatic populations (n=72),

61.4% (95% CI: 53.4-69.1%) in higher-risk populations (n=40; mainly FSWs), and 71.3% (95% CI: 66.5-75.9%) in HIV positive individuals and in individuals in HIV discordant couples (n=42; Table 2).

Among general populations, the pooled mean seroprevalence varied across African subregions (Table 3), with the lowest being 25.0% (95% CI: 20.9-29.4%) in Western Africa (n=68), followed by 35.8% (95% CI: 31.6-40.0%) in Southern Africa (n=226), 41.9% (95% CI: 38.4-45.3%) in Eastern Africa (n=188), and 52.4% (95% CI: 40.4-64.3%) in Central Africa (n=25). Similar hierarchy was observed across subregions for women and men, with women having consistently higher pooled mean seroprevalence compared to men (Table S9).

Across age groups (Table 3), pooled mean seroprevalence increased gradually from 12.4% (95% CI: 10.6-14.3%) in those <20 years-old (n=88), followed by 34.2% (95% CI: 30.7-37.8%) in those 20-30 years-old (n=112), 57.1% (95% CI: 54.8-63.3%) in those 30-40 years-old (n=69), 64.6% (95% CI: 59.5-69.5%) in those 40-50 years-old (n=48), to then decrease slightly to 58.2% (95% CI: 50.3-65.9%) in those >50 years-old. A similar trend was observed across age groups for each of women and men, but seroprevalence grow faster with age for young women (Table S9).

Heterogeneity was evident in almost all meta-analyses (p-value<0.001), and was confirmed by the wide prediction intervals (Tables 2, 3, and S9). Most heterogeneity was attributed to true variation in seroprevalence rather than chance ($I^2>50\%$). Forest plots for meta-analyses across African subregions stratified by population type are in Figure S2.

Predictors of HSV-2 seroprevalence

Table 4 shows results of the meta-regression analyses for HSV-2 seroprevalence. Nine variables were eligible for inclusion in the multivariable model (p-value<0.1 in univariable analysis). Two multivariable models were conducted, one including year of publication as a categorical variable and one including it as a linear term.

The model including year of publication as a categorical variable explained 57.5% of seroprevalence variation and included population type, age group, sex, African subregion, country's income, assay type, sampling method, response rate, and year of publication category (Table 4). Compared to general populations who had the lowest seroprevalence, seroprevalence was highest in HIV positive individuals and in individuals in HIV discordant couples [adjusted risk ratio (ARR) of 2.17 (95% CI: 1.78-2.65)], followed by STI clinic attendees and symptomatic populations, higher-risk populations, intermediate-risk populations, and HIV negative populations.

Compared to women, men had a 0.61-fold (95% CI: 0.56-0.67) lower seroprevalence.

Seroprevalence increased rapidly with age at young age, but the increase plateaued by age 40-50 years. Seroprevalence was highest in Eastern Africa, followed by Southern Africa, Central Africa, and lowest in Western Africa. Country's income was not associated with seroprevalence.

Studies that had a lower or unknown response rate had a higher seroprevalence. Meanwhile, assay type, study sample size, and study sampling method were not associated with seroprevalence.

Compared to those published before the year 2005, studies published in 2006-2015 [ARR of 0.85 (95% CI: 0.76-0.96)] and after 2015 [ARR of 0.80 (95% CI: 0.69-0.93)] had lower seroprevalence.

The model including year of publication as a linear term (Table 4) showed similar results and indicated declining seroprevalence with time [ARR of 0.98 (95% CI: 0.97-0.99)]. The model explained 57.5% of seroprevalence variation

Sensitivity analyses including year of data collection as a categorical variable or as a linear term (in replacement of year of publication) arrived at similar results (Table S10).

Overview and meta-analyses of HSV-2 isolation in genital ulcer disease and in genital herpes

Table S11 summarizes extracted proportions of HSV-2 detection in GUD and in genital herpes. In GUD cases (n=31), proportion of HSV-2 detection ranged between 8.3-100% with a median of 49.1% and a pooled mean proportion of 50.7% (95% CI: 44.7-56.8%) (Table 5). Among women (n=8), it ranged between 35.0-100% with a median of 49.5% and a pooled proportion of 59.0% (95% CI: 44.7-72.6%), and among men (n=13), it ranged between 8.3-72.2% with a median of 49.1% and a pooled proportion of 47.3% (95% CI: 37.2-57.5%).

In genital herpes cases (n=11), proportion of HSV-2 detection ranged between 53.0-100% with a median of 100% and a pooled mean proportion of 97.3% (95% CI: 84.4-100%) (Table 5). No study distinguished between primary and recurrent genital herpes episodes.

These meta-analyses showed evidence of heterogeneity (p-value<0.001, I²>50%, and wide prediction intervals). Forest plots are in Figure S3.

Quality assessment

Quality assessment of diagnostic methods excluded 51 publications due to potential issues in the implemented diagnostic assays. Quality assessment of included seroprevalence measures is summarized in Table S12. Briefly, 288 studies (89.4%) had high precision, 88 studies (27.3%)

and 85 studies (26.4%) had low ROB in the sampling method and in the response rate domains, respectively. Twenty-three studies (7.1%) had high ROB in both quality domains.

Discussion

This systematic review presented a detailed assessment of HSV-2 epidemiology in sub-Saharan Africa. Strikingly, the results demonstrate that HSV-2 seroprevalence has been declining by about 2% per year over the last three decades (Table 4). This decline is in line with the observed declines in HIV epidemics in SSA during the same timeframe.⁽⁶²⁾ Drivers of the decline in HIV prevalence have been subject to debate, with various mechanisms posited including natural epidemic dynamics,⁽⁶³⁾ increased HIV-associated mortality,^(64, 65) impact of interventions,⁽⁶⁵⁾ heterogeneity in host susceptibility to HIV infection,^(66, 67) and reductions in sexual risk behavior.^(65, 68-71) Considering that HSV-2 seroprevalence has been shown to provide an *objective proxy biomarker* of population-level sexual risk behavior,⁽¹⁹⁻²⁴⁾ our finding of rapidly declining HSV-2 seroprevalence suggests that sexual risk behavior has been declining, and that this decline has reduced the transmission of both HIV and HSV-2 infections. With evidence of HSV-2 infection increasing risk of HIV acquisition and transmission,⁽¹⁰⁻¹³⁾ it remains to be seen whether the declining HSV-2 incidence may have also contributed to the declines seen in HIV incidence in SSA.

Despite declining HSV-2 transmission in SSA, incidence rate is still high (Table 1), and much higher than that found elsewhere in the world.⁽¹⁾ For instance, the incidence rate in the United States (<1 per 100 person-years)⁽⁷²⁾ is an order of magnitude lower than that in SSA. The results further demonstrate that age plays a profound effect in HSV-2 epidemiology—age alone accounted for 30% of the seroprevalence variation (Table 4). HSV-2 infection in SSA is

typically acquired at a young age not long after sexual debut, especially so for women, manifesting in a rapidly increasing seroprevalence with age before plateauing at high levels by ages 40-50 (Tables 1, 3, 4, and S9).

Population risk classification was also found to play an important role in HSV-2 epidemiology, accounting for 13% of seroprevalence variation (Table 4). Both incidence rate and seroprevalence were found at much higher levels in specific at-risk populations, such as female sex workers (Tables 2 and 4), with both measures displaying the “classical hierarchy” of STI exposure by sexual risk behavior, also seen with other STIs.(73, 74) Despite its prominence amongst higher risk populations, HSV-2 infection is also widely disseminated in SSA with high levels of infection even in the lower risk general population where over a quarter of men and nearly half of women are infected (Tables 2 and 4).

Although HSV-2 seroprevalence is high everywhere in SSA, there are still considerable variations by subregion. Infection levels were highest in Eastern Africa followed by Southern Africa, Central Africa, and lowest in Western Africa (Table 4). Incidentally, this pattern is also seen for HIV infection with Eastern Africa and Southern Africa being most affected and Western Africa least affected.(75, 76) This further suggests a strong link between HSV-2 and HIV epidemiologies,(24) reflecting a similar mode of transmission and hinting at a biological/epidemiological synergy.(10-14) The results further demonstrate that women are almost twice as likely to be infected as men (Table 4), reflecting a higher bio-anatomical susceptibility to the infection.(77, 78)

Another finding of this study is that HSV-2 infection is the cause of half of GUD cases in SSA (Table 5), confirming that this infection is the main cause of this disease in this part of the world where nearly 60 million individuals are estimated to be affected with HSV-related GUD.(79)

Although HSV-2 seroprevalence is declining (Table 4), it will likely remain the main cause of GUD in SSA, as other causes such as syphilis have also been declining.(80, 81) HSV-2 infection (as opposed to HSV-1 infection) was also found to account for nearly all cases of genital herpes (>97%; Table 5). This finding is presumably due to the nature of HSV-1 being widely acquired in childhood in SSA through oral transmission,(33) and distinguishes this region from other global regions where there is an increasing role for HSV-1 in genital herpes,(33-36) with some countries already observing HSV-1 as the cause of a large proportion of cases of genital herpes.(33-36)

This study had limitations, principally the unavailability of data for 15 of 45 African countries. There was also less data for Central and Western Africa than for Eastern and Southern Africa, in addition to data for seroprevalence eclipsing those of GUD and genital herpes. Despite these limitations, a large volume of data was available to sufficiently power an array of analyses. Included studies exhibited heterogeneity (Tables 2, 3, and S9); however, more than half of this heterogeneity (57%) was subsequently explained through meta-regressions (Table 4). Studies differed by assay type, sample size, sampling method, and response rate, yet none of these study characteristics appeared to affect seroprevalence with the exception of response rate where studies with lower or unknown response rate had a higher seroprevalence (Table 4). Overall, these limitations should not pose a barrier to the critical interpretation of this study's results, or its findings.

Conclusions

In conclusion, HSV-2 seroprevalence is declining rapidly in SSA. Yet, HSV-2 incidence and seroprevalence remain at high levels, with over a third of the population being infected. Age and subregion within SSA play a critical role in HSV-2 epidemiology and explain much of the

observed variation in seroprevalence. The geographical distribution of this infection was also found to be similar to that of HIV infection, and the declines in HSV-2 seroprevalence mirrored those for HIV prevalence. These findings suggest that the declines in both infections were driven by reductions in sexual risk behavior following the massive expansion of the HIV epidemic in this continent, and may suggest that some of the declines in HIV incidence could have been attributed to the declines in HSV-2 incidence. HSV-2 infection was found to be the etiological cause of half of GUD cases in this region, and virtually all cases of genital herpes. These findings demonstrate the urgent need for both prophylactic and therapeutic HSV-2 vaccines to tackle the disease burden of this infection,(82) and argue for further acceleration of ongoing efforts for vaccine development.(26, 27, 83)

Contributors

MH and FAH conducted the systematic search, data extraction, and data analysis. MH wrote the first draft of the paper. CJ and KJL contributed to the systematic search, data extraction, and interpretation of the results. LJA conceived the study and led the data extraction and analysis and interpretation of the results. All authors contributed towards drafting and revising the manuscript.

* Q: the Cochran's Q statistic is a measure assessing the existence of heterogeneity in seroprevalence.

† I²: a measure that assesses the magnitude of between-study variation that is due to actual differences in seroprevalence across studies rather than chance.

‡ Prediction interval: a measure that estimates the distribution (95% interval) of true seroprevalence around the estimated mean.

§ No meta-analysis was done due to the small number of studies (n < 3).

¶ Symptomatic populations include patients with clinical manifestations related to an STI.

Abbreviations: CI = Confidence interval, FSWs = Female sex workers, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, MSM = Men who have sex with men, STI = Sexually transmitted disease.

Table 3. Pooled mean estimates for herpes simplex virus type 2 seroprevalence among general populations in sub-Saharan Africa.

^{*} Variance explained by multivariable model 1 (adjusted R²) = 57.47%.

[†] Variance explained by multivariable model 2 (adjusted R²) = 57.50%.

[‡] Sample size denotes the sample size of each study population found in the original publication.

Abbreviations: ARR = Adjusted risk ratio, CI = Confidence interval, ELISA = Enzyme-linked immunosorbent type-specific assay, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, LIC = Low-income country, LMIC = Lower-middle-income country, LR = Likelihood ratio, RR = Risk ratio, STI = Sexually transmitted infection, UMIC = Upper-middle-income country.

Table 5. Pooled proportions of herpes virus type 2 (HSV-2) virus isolation in clinically-diagnosed GUD and in clinically-diagnosed genital herpes in Africa.

Population type	Outcome measures	Sample size	Proportion of HSV-2 isolation (%)		Pooled proportion of HSV-2 isolation (%)	Heterogeneity measures		
	Total n	Total N	Range	Median	Mean (95% CI)	Q* (p-value)	I ² † (%) (95% CI)	Prediction Interval‡ (%)
Patients with GUD	31	4,296	8.3-100	49.1	50.7 (44.7-56.8)	423.6 (p<0.001)	92.9 (91.0-94.4)	19.7-81.5
Women	8	816	35.0-100	49.5	59.0 (44.7-72.6)	88.1 (p<0.001)	92.1 (86.7-95.2)	13.0-100
Men	13	1,915	8.3-72.2	49.1	47.3 (37.2-57.5)	225.1 (p<0.001)	94.7 (92.4-96.2)	11.4-84.8
Mixed sexes	10	1,565	22.4-73.0	50.0	49.1 (39.0-59.2)	110.3 (p<0.001)	91.8 (87.1-94.8)	15.5-83.2
Patients with genital herpes	11	1,380	53.0-100	100	97.3 (84.4-100)	586.5 (p<0.001)	98.3 (97.8-98.7)	22.8-100
Men	6	715	53.0-100	100	97.3 (73.4-100)	318.8 (p<0.001)	98.4 (97.7-98.9)	0.0-100
Mixed sexes	5	665	91.4-100	85.4	97.8 (91.9-100)	23.9 (p<0.001)	83.3 (62.0-92.6)	66.2-100

*Q: The Cochran's Q statistic is a measure assessing the existence of heterogeneity in pooled outcome measures, here proportions of HSV-2 virus isolation.

†I²: A measure assessing the magnitude of between-study variation that is due to true differences in proportions of HSV-2 virus isolation across studies rather than sampling variation.

‡Prediction interval: A measure quantifying the distribution 95% interval of true proportions of HSV-2 virus isolation around the estimated pooled mean.

Abbreviations: CI = Confidence interval, GUD = Genital ulcer disease, HSV-2 = Herpes simplex virus type 2.

Table S1. Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) checklist.(1)

Section/topic	#	Checklist item	Reported in main text on
Title			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	p.1
Abstract			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	p.2-3
Introduction			
Rationale	3	Describe the rationale for the review in the context of what is already known.	p. 3
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	p. 3
Methods			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	NA
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	p. 4
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	p. 3-4
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Supplementary Table 2
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	p. 4
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	p. 5; Supplementary Box 2
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	p. 5; Supplementary Box 2
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	p. 5-6
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	p. 6
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I^2) for each meta-analysis.	p. 6
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	p. 5-6
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating	p. 7

		which were pre-specified.	
Results			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	p. 8; Figure 2
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	p. 8 and 9; Tables 1 and 4
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	p. 10-11; Supplementary Table 3
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	p. 8-10; Tables 2 and 5; Supplementary Figures 1 and 2
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	P. 8 and 10; Tables 2 and 5
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	p. 10-11; Supplementary Table 3
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	p. 9-10; Table 3
Discussion			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	p. 11
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	p. 13
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	p. 11-13
funding			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	p. 14

Abbreviations: NA = Not applicable, p = page.

Abbreviations: HSV-2 = Herpes simplex virus type 2.

Box S1. List of the 45 countries included in our definition for sub-Saharan Africa by subregion.(2)

Eastern Africa: Comoros, Ethiopia, Eritrea, Kenya, Madagascar, Mauritius, Rwanda, Seychelles, Tanzania, and Uganda.

Southern Africa: Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Eswatini (formerly known as Swaziland), Zambia, and Zimbabwe.

Western Africa: Benin, Burkina Faso, Cabo Verde, Cote d'Ivoire, Gambia, Ghana, Guinea-Bissau, Guinea, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, and Togo.

Central Africa: Burundi, Cameroon, Central African Republic, Chad, Congo, Democratic Republic of Congo, Equatorial Guinea, Gabon, and Sao Tome-and Principe.

Northern Africa: Mauritania.

Box S2. List of variables extracted from the relevant publications meeting the inclusion criteria.

1. Author(s)
2. Publication title
3. Publication year
4. Year(s) of data collection
5. Country of origin
6. Country of survey
7. City
8. Study site
9. Study design
10. Study sampling procedure
11. Study population
12. Population demographic characteristics (e.g., sex and age)
13. Diagnostic assay
14. Sample size
15. HSV-2 outcome measures

Abbreviations: HSV-2 = Herpes simplex virus type 2

Box S3. Definitions of population type classifications.

1. **General populations** (populations at low risk): these include populations at lower risk of exposure to HSV-2, such as antenatal clinic attendees, blood donors, and pregnant women, among others.
2. **Intermediate-risk populations:** these include populations who presumably have frequent sexual contacts with populations engaging in high sexual risk behavior, and have therefore a higher risk of exposure to HSV-2 than the general population. These comprise prisoners, people who inject drugs, and truck drivers, among others.
3. **Higher-risk populations:** these include populations at high risk of exposure to HSV-2 as a consequence of specific sexual risk behaviors such as female sex workers, men who have sex with men, male sex workers, and transgender populations, among others.
4. **HIV negative populations:** these include populations with confirmed HIV negative status as part of the study's inclusion criteria.
5. **HIV positive individuals and individuals in HIV discordant couples:** these include populations who are HIV positive or are in a spousal relationship with an HIV positive individual.
6. **STI clinic attendees and symptomatic populations:** these include patients attending STI clinics, or have clinical manifestations related to an STI.
7. **Other populations:** these include populations not satisfying above definitions, or populations with an undetermined risk of acquiring HSV-2 infection.

Abbreviations: HSV-2 Herpes simplex virus type 2, STI = Sexually transmitted infection, HIV = Human immunodeficiency virus.

Box S4. Variables included in the univariable and multivariable meta-regression analyses.

- 1- Population type as defined in Box S3
- 2- Sex
- 3- Age groups classified to best fit reported data as:
 - <20 years-old
 - 20-30 years-old
 - 30-40 years-old
 - 40-50 years-old
 - >50 years-old
 - Mixed age bands
- 4- African subregion as defined in Box S1
- 5- Country's income as classified by the World Bank(3)
- 6- Assay type:
 - Western Blot
 - ELISA
 - Rapid test
- 7- Sample size:
 - ≥ 100
 - <100
- 8- Sampling method;
 - Probability-based sampling
 - Non-probability based sampling
- 9- Response rate:
 - $\geq 80\%$
 - <80%
 - Unclear
- 10- Year of publication category:
 - ≤ 2005
 - 2006-2015
 - >2015
- 11- Year of publication as a linear term
- 12- Year of data collection category*
 - <2000
 - 2000-2010
 - >2010
- 13- Year of data collection as a linear term

* The categories were set based on the observed median time between the year of publication and year of data collection of 5 years.
Abbreviations: ELISA = Enzyme-linked immunosorbent assay

Table S3. Studies reporting HSV-2 seroconversion rate or incidence rate in sub-Saharan Africa.

Author, year	Year(s) of data collection	Country	Original study design	Population characteristics	HSV-2 serological assay	Sample size	Follow-up duration	Person-years of follow-up	HSV-2 seroconversion rate (%)	HSV-2 incidence rate (per 100 person-years)

Other populations									
Kassa, 2019(113)	2005-09	Ethiopia	Outpatient clinic/Hospital	CS	Conv	HIV negative and HIV positive pregnant women	ELISA	2,532	41.5
Okuku, 2011(48)	2005-08	Kenya	Outpatient clinic	Cohort	Conv	Adults engaging in different risky sexual behaviors	ELISA	1,272	32.6
Van de Wijgert, 2009(26)	1999-04	Uganda	Outpatient clinic	Cohort	Conv	FSWs and healthy women	ELISA	2,199	48.7

[‡] The reported study design is the original study design (case control, cross sectional, longitudinal cohort, or randomized controlled trial). The included seroprevalence measures are those for the baseline measures at the beginning of the study.

[†] Symptomatic populations include patients with clinical manifestations related to an STI.

Abbreviations: CC = Case control, Conv = Convenience, CRS = Cluster random sampling, CS = Cross sectional, DSS = Demographic surveillance system, EIA = Enzyme immunoassay, ELISA = Enzyme-linked

immunosorbent assay, FSWs = Female sex workers, GUD = Genital ulcer disease, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, MOH = Ministry of Health, PROM = Premature rupture of membranes, RCT = Randomized controlled trial, RS = Random sampling, STI = Sexually transmitted infection, VCT = Voluntary counselling and testing, WB = Western blot.

Table S5. Studies reporting HSV-2 seroprevalence in Southern Africa. This table includes only overall and not stratified seroprevalence measures,

Author, year	Year(s) of data collection	Country	Study site	Original study design*	Sampling method	Population	HSV-2 serological assay	Sample size	HSV-2 seroprevalence (%)

* The reported study design is the original study design (case control, cross sectional, longitudinal cohort, or randomized controlled trial). The included seroprevalence measures are those for the baseline measures at the beginning of the study.

[†] The four African countries are: Malawi, South Africa, Zambia, and Zimbabwe.

[‡] Symptomatic populations include patients with clinical manifestations related to an STI.

Abbreviations: ANC = Antenatal clinic, CC = Case control, Conv = Convenience, CRS = Cluster random sampling, CS = Cross sectional, DSS = Demographic surveillance system, EIA = Enzyme immunoassay, ELISA = Enzyme-linked immunosorbent assay, FSWs = Female sex workers, GUD = Genital ulcer disease, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, IB = Immunoblot, US = Urethritis syndrome, NIMH = National Institute of Mental Health, RCT = Randomized controlled trial, RDT = Rapid diagnostic test, RS = Random sampling, STI = Sexually transmitted infection, VCT = Voluntary counselling and testing, VDS = Vaginal discharge syndrome, WB = Western blot.

Table S6. Studies reporting HSV-2 seroprevalence in Western Africa. This table includes only overall and not stratified seroprevalence measures.

[†] Symptomatic populations include patients with clinical manifestations related to an STI.

Abbreviations: Conv = Convenience, CRS = Cluster random sampling, CS = Cross sectional, EIA = Enzyme immunosorbent assay, ELISA = Enzyme-linked immunosorbent assay, FSWs = Female sex workers, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, RS = Random sampling, STI = Sexually transmitted infection, WB = Western blot.

Table S8. Studies reporting HSV-2 seroprevalence across several regions in sub-Saharan Africa. This table includes only overall and not stratified seroprevalence measures.

Author, year	Year(s) of data collection	Country	Study site	Original study design*	Sampling method	Population	HSV-2 serological assay	Sample size	HSV-2 seroprevalence (%)
HIV negative populations									
ECHO trial consortium(206)	2015-17	4 African countries [†]	Community	RCT	Conv	Females using injectable contraceptives	ELISA	2,588	38.7
ECHO trial consortium(206)	2015-17	4 African countries [†]	Community	RCT	Conv	Females using intrauterine contraceptives	ELISA	2,587	39.4
ECHO trial consortium(206)	2015-17	4 African countries [†]	Community	RCT	Conv	Females using implantable contraceptives	ELISA	2,584	37.4
Marrazzo, 2015(207)	2009-11	3 African countries [‡]	Community	RCT	Conv	Female trial participants	ELISA	5,005	46.0
McCormack, 2010(40)	2005-09	4 African countries [§]	Outpatient clinic/Community	RCT	Conv	Female trial participants receiving 2% gel	ELISA	2,725	60.0
McCormack, 2010(40)	2005-09	4 African countries [§]	Outpatient clinic/Community	RCT	Conv	Female trial participants receiving 0.5% gel	ELISA	3,312	61.0
McCormack, 2010(40)	2005-09	4 African countries [§]	Outpatient clinic/Community	RCT	Conv	Female trial participants receiving placebo	ELISA	3,311	60.0
HIV positive individuals and individuals in HIV discordant couples									
Heffron, 2012(208)	2004-10	7 African countries [¶]	Community	Cohort	Conv	Males with an HIV positive partner	WB	2,393	60.2
Heffron, 2012(208)	2004-10	7 African countries [¶]	Community	Cohort	Conv	Females with an HIV positive partner	WB	1,283	84.8
STI clinic attendees and symptomatic populations[‡]									
LeGoff, 2007(209)	2003-05	2 African countries ^{**}	Outpatient clinic	RCT	Conv	Women with GUD	ELISA	437	79.0

* The reported study design is the original study design (case control, cross sectional, longitudinal cohort, or randomized controlled trial). The included seroprevalence measures are those for the baseline measures at the beginning of the study.

[†] The four African countries are Eswatini, South Africa, Kenya, and Zambia.

[‡] The three African countries are South Africa, Uganda, and Zimbabwe.

[§] The four African countries are South Africa, Tanzania, Uganda, and Zimbabwe.

[¶] The seven African countries are: Botswana, Kenya, South Africa, Tanzania, Uganda, and Zambia.

[‡] Symptomatic populations include patients with clinical manifestations related to a sexually transmitted infection.

** The two African countries are Ghana and Central African Republic

Abbreviations: Conv = Convenience, ELISA = Enzyme-linked immunosorbent assay, GUD = Genital ulcer disease, HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, RCT = Randomized controlled trial, WB = Western blot.

Table S9. Pooled mean estimates for herpes simplex virus type 2 seroprevalence among general populations by sex stratification in sub-Saharan Africa.

	Among women						Among men

^{*}I²: a measure that assesses the magnitude of between-study variation that is due to actual differences in seroprevalence across studies rather than chance. All meta-analyses had a statistically significant Cochrane's Q-statistic (p<0.001) and a wide prediction interval indicative of strong heterogeneity.

[†]Other countries: Cote d'Ivoire, Eritrea, Gabon, Mali.

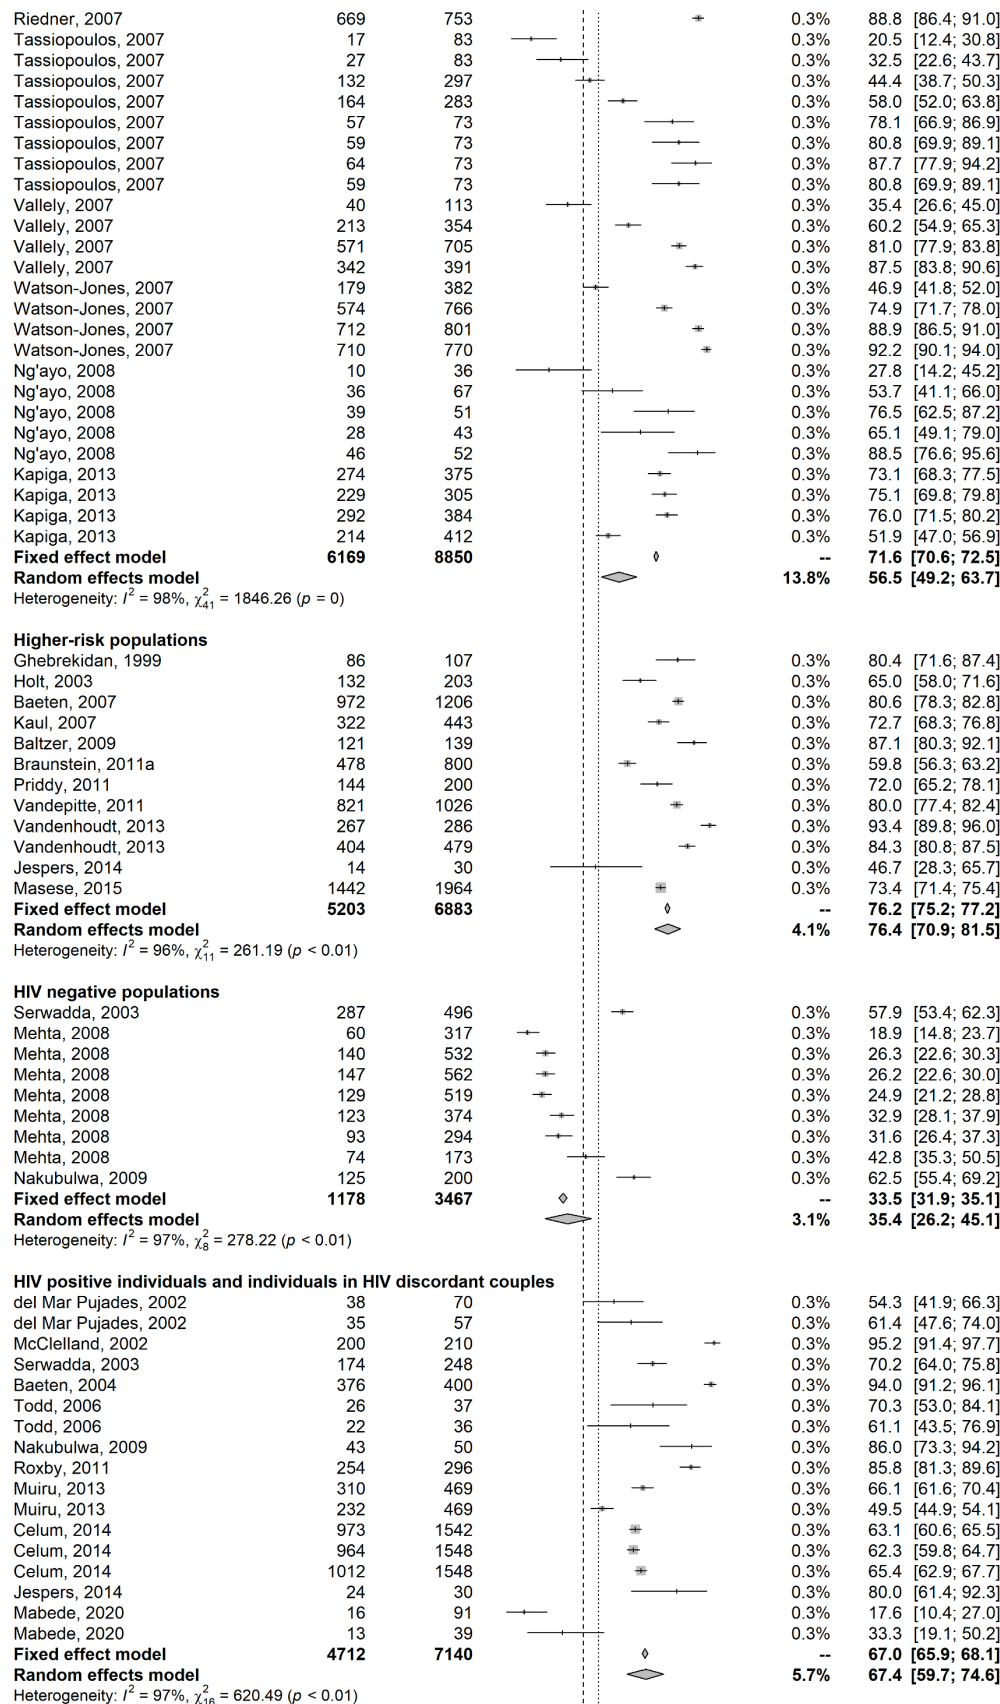

Abbreviations: CI = Confidence interval, HSV-2 = Herpes simplex virus type 2.

Figure S2. Forest plots presenting the outcomes of the pooled mean herpes simplex virus type 2 (HSV-2) seroprevalence among the different at risk populations across the sub-Saharan Africa subregions.

A) Eastern Africa

Abbreviations: HIV = Human immunodeficiency virus, HSV-2 = Herpes simplex virus type 2, STI = Sexually transmitted infection.

B) Southern Africa

[†] Variance explained by the multivariable model (adjusted R²) = 57.68%.

[‡] Variance explained by multivariable model 2 (adjusted R²) = 57.58%.

[‡] Sample size denotes the sample size of each study population found in the original publication.

[§] The categories were set based on the observed median time between the year of publication and year of data collection of 5 years.

Abbreviations: ARR = Adjusted risk ratio, CI = Confidence interval, ELISA = Enzyme-linked immunosorbent assay, HSV-2 = Herpes simplex virus type 2, HIV = human immunodeficiency virus, LIC = Low-income country, LMIC = Lower-middle-income country, LR = Likelihood ratio, RR = Risk ratio, STI = Sexually transmitted infection, UMIC = Upper-middle-income country.

Table S11. Studies reporting proportions of HSV-2 virus isolation in clinically-diagnosed genital ulcer disease and in clinically-diagnosed genital herpes in sub-Saharan Africa.

Author, year	Year(s) of data collection	Country	Study site	Study design	Sampling method	Population	HSV-2 biological assay	Sample size	Proportion of HSV-2 detection (%)
Patients with clinically-diagnosed GUD									
Ahmed, 2003(210)	1999	Tanzania	Outpatient clinic	CS	Conv	Patients with GUD	PCR	50	73.0
Ahmed, 2003(210)	1999	Tanzania	Outpatient clinic	CS	Conv	Patients with GUD	PCR	52	42.0
Chen, 2000(160)	1993-94	South Africa	Outpatient clinic	CS	Conv	Men with GUD	PCR	538	35.9
Gray, 2009(211)	2002-06	Uganda	Community	CS	Conv	Circumcised men with GUD	PCR	25	48.0
Gray, 2009(211)	2002-06	Uganda	Community	CS	Conv	Uncircumcised men with GUD	PCR	56	39.4
Kamya, 1995(212)	1990-91	Uganda	Outpatient clinic	CS	Conv	Patients with GUD	IF	98	32.7
Kularatne, 2018(163)	2007-15	South Africa	Outpatient clinic	CS	Conv	Patients with GUD	PCR	771	60.7
LeGoff, 2007(209)	2003-05	Ghana and Central African Republic	Outpatient clinic	CS	Conv	Women with GUD	PCR	422	50.0
Masaka, 2012(213)	2010	Zambia	Outpatient clinic	CS	Conv	Patients with GUD	PCR	200	28.0
Mayaud, 2008(214)	-	Burkina Faso	Community	CS	Conv	Women with GUD	PCR	37	49.0
Mungati, 2018(215)	2014-15	Zimbabwe	Outpatient clinic	CS	Conv	Patients with GUD	PCR	200	38.5
Mwansasu, 2002(111)	-	Tanzania	Community	CS	Conv	Patients with GUD	PCR	70	64.3
Nilsen, 2007(216)	1999-01	Tanzania	Outpatient clinic	CS	Conv	Patients with GUD	PCR	301	64.0
O'Farrell, 2007(168)	2004	South Africa	STI clinic	CS	Conv	Males with GUD	PCR	162	52.7
Oni, 1997(217)	1992	Nigeria	Outpatient clinic	CS	Conv	Males attending an STI clinic	CF and IF	24	8.3
Paz-Bailey, 2005(218)	2001-02	Botswana	Outpatient clinic	CS	Conv	Patients with GUD	PCR	137	58.0
Paz-Bailey, 2009(169)	2005-06	South Africa	Outpatient clinic	CS	RS	Men with GUD taking acyclovir	PCR	309	69.9
Paz-Bailey, 2009(169)	2005-06	South Africa	Outpatient clinic	CS	RS	Men with GUD taking a placebo	PCR	306	72.2
Phiri, 2013(170)	2004-06	Malawi	Outpatient clinic	CS	Conv	Males and Females with GUD	PCR	398	67.0
Pickering, 2005(219)	1999-01	Uganda	Outpatient clinic	CS	Conv	Adult males and females presenting with GUD	PCR	202	47.0
Suntoke, 2009(112)	2002-06	Uganda	Community	CS	Conv	>19 years old patients with GUD	PCR	100	62.0
Tanton, 2010(220)	2004-06	Tanzania	Community	CS	Conv	Women working in recreational facilities	PCR	22	18.2
Vandenhoudt, 2013(100)	2008	Kenya	Community	CS	RDS	FSWs with GUD	PCR	22	40.9
Vandepitte, 2011(101)	2008-09	Uganda	Community	CS	Conv	FSWs with GUD	PCR	62	35.0
Zimba, 2011(171)	2005	Mozambique	Outpatient clinic	CS	Conv	Patients with GUD	PCR	76	62.0
Patients with clinically-diagnosed genital herpes*									
Chen, 2000(160)	1993-94	South Africa	Outpatient clinic	CS	Conv	Men with genital herpes	PCR	193	100.0
Kamya, 1995(212)	1990-91	Uganda	Outpatient clinic	CS	Conv	Males and females with genital herpes	IF	35	91.4
Kularatne, 2018(163)	2007-15	South Africa	Outpatient clinic	CS	Conv	Patients with genital herpes	PCR	468	100.0
Lai, 2003(221)	1998	South Africa	Outpatient clinic	CS	Conv	Genital herpes swabs collected in 1998	PCR	57	100.0
Lai, 2003(221)	1993-94	South Africa	Outpatient clinic	CS	Conv	Genital herpes swabs collected in 1993	PCR	14	100.0
Morse, 1997(167)	1993-94	Lesotho	Outpatient clinic	CS	Conv	Patients with genital herpes	PCR	20	95.0
Mungati, 2018(215)	2014-15	Zimbabwe	Outpatient clinic	CS	Conv	Patients with genital herpes	PCR	77	98.7
Paz-Bailey, 2009(169)	2005-06	South Africa	Outpatient clinic	CS	RS	Men with genital herpes	PCR	451	53.0
Suntoke, 2009(112)	2002-06	Uganda	Community	CS	Conv	Patients with GUD testing positive for HSV	PCR	65	95.4

* Included studies did not distinguish between primary and recurrent genital herpes cases.

Abbreviations: CF = Complement fixation, Conv = Convenience, CS = Cross sectional, FSWs = Female sex workers, GUD = Genital ulcer disease, HSV-2 = Herpes simplex virus type 2, IF = Immunofluorescence, PCR = Polymerase chain reaction, RCT = Randomized controlled trial, RS = Random sampling, STI = Sexually transmitted infections.

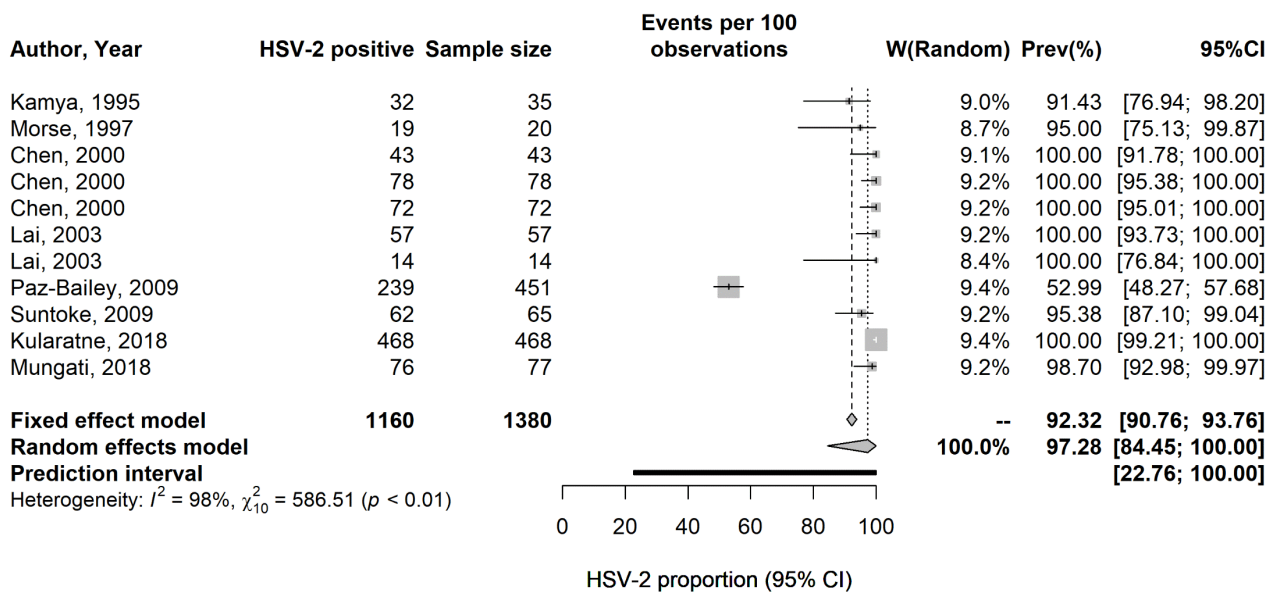

Figure S3. Forest plots presenting the outcomes of the pooled mean proportions of HSV-2 virus isolation in clinically-diagnosed genital ulcer disease (GUD) and in clinically-diagnosed genital herpes in sub-Saharan Africa.

A) Patients with GUD

Abbreviations: HSV-2 = Herpes simplex virus type 2.

B) Patients with genital herpes

Abbreviations: HSV-2 = Herpes simplex virus type 2.

Table S12. Summary of the precision assessment and risk of bias assessment for the studies reporting HSV-2 seroprevalence in sub-Saharan Africa.

Quality assessment	HSV-2 seroprevalence measures	
	Number of studies	%
Precision of seroprevalence measures^a		
Low precision	34	10.6
High precision	288	89.4
Risk of bias quality domain^b		
Sampling method		
Low risk of bias	88	27.3
High risk of bias	234	72.7
Response rate		
Low risk of bias	85	26.4
High risk of bias	45	14.0
Unclear risk of bias	192	59.6
Summary of the risk of bias assessment		
Low risk of bias		
In at least one quality domain	107	33.2
In both quality domains	39	12.1
High risk of bias		
In at least one quality domain	91	28.3
In both quality domains	23	7.1
Seroprevalence studies where risk of bias assessment was possible	322	100

^aPrecision was assessed based on the overall sample size (not each stratum subsample size) of the study as reported in the record/publication.

^bRisk of bias was assessed based on the overall sample size (not each stratum subsample size) of the study as reported in the record/publication.

Abbreviations: HSV-2 = Herpes simplex virus type 2.
