57 **ABSTRACT**

58

59 **Background.** In the hand, the Systemic Sclerosis (SS) is characteristically evidenced by Raynaud's  
60 phenomenon (RP) and fibrosis of the skin, tendons, ligaments, and joints as well as digital ulcers  
61 with prolonged healing. Current medical treatment not always cure these complications. Local  
62 adipose-derived stromal vascular fraction (ADSVF) administration into the hands has been  
63 proposed as an emerging treatment for these complications, due to its proangiogenic,  
64 antifibrotic, and immunoregulatory activities. The objective of this controlled trial was to  
65 evaluate the safety and clinical effects of fat micrografts plus ADSVF administration into the  
66 hands of patients with SS.

67 **Methods.** This was an open-label, monocentric, randomized controlled study. Twenty patients  
68 diagnosed with SS were enrolled and assigned to the experimental or control group. Fat  
69 micrografts plus the ADSVF were injected into the right hand of experimental group patients.  
70 The control group continued to receive only medical treatment. Demographic, serologic data  
71 and disease severity were recorded. Digital oximetry, pain, Raynaud phenomenon (RP), digital  
72 ulcer healing (DUH), mobility, thumb opposition, vascular density of the nail bed, skin affection  
73 of the hand, Serologic antibodies, hand function, and quality of life scores were evaluated in  
74 both groups. The mean follow-up period was 168 days.

75 The differences between before and after the intervention were analyzed with the Wilcoxon  
76 range test, and the differences between the control and experimental groups at 0 days and 168  
77 days were analyzed with the Mann–Whitney U test.

78 **Results.** Adverse events were not observed in both groups. There were no changes in disease  
79 severity, serologic antibodies, nailfold capillaroscopy patterns, mobility, and hand function in  
80 both groups. There were significant improvements in pain, DUH and quality of life scores in the  
81 experimental group. RP improved significantly in both groups. However, on statistically  
82 comparing the results at 168 days between the groups, significant improvements were only  
83 observed in pain levels ( $p = 0.02$ ) and DUH ( $p=0.003$ ).

84 **Conclusions.** The injection of ADSVF plus fat micrografts is a reproducible, and safe technique.  
85 Pain and digital ulcers in the hands of patients with SS can be treated with this treatment.

86 **Trial Registration:** Retrospectively registered in ClinicalTrials.gov with identifier NCT04387825

87 **Keywords:** hand therapy; adipose derived vascular stromal fraction; systemic sclerosis; adipose  
88 mesenchymal stem cells; regenerative medicine.

90

91

## 92 INTRODUCTION

93 Systemic sclerosis (SS) is characterized by the presence of functional and structural  
94 microvasculopathy resulting in ischemia that leads to cutaneous and visceral fibrosis. In the  
95 hand, this disease is characteristically evidenced by Raynaud's phenomenon (RP) and fibrosis of  
96 the skin, tendons, ligaments, and joints.[[1,2,3,4](#)] Further, the hand is affected in 47 to 97% of  
97 the SS cases.[[5, 6](#)] Permanent ischemia and skin fibrosis can lead to the appearance of digital  
98 ulcers that result in prolonged healing durations, recurrences, and infections and may culminate  
99 in digital amputation. This musculoskeletal involvement is one of the main etiologies of pain,  
100 devastating disability, and a dramatic decrease in the quality of life of patients with SS.[[6, 7](#)]-The  
101 current treatment is the control of the disease with medications and rehabilitation.[[8](#)] However,  
102 these options only temporarily control the symptoms but do not decrease the time period  
103 required for ulcer healing or improve hand function.

104 The presence of adipose stem cells (ASCs) in the adipose-derived stromal vascular fraction  
105 (ADSVF) was described by Zuk et al. in 2002.[[9](#)] Because these cells are multipotent with local  
106 angiogenic, anti-inflammatory, antifibrotic, immunomodulatory, and regenerative properties  
107 and because of their abundance in fat, easy acquisition, and almost immediate availability for  
108 use, ADSVF administration has positioned itself as an alternative treatment for immunological  
109 diseases that cause ischemia and cutaneous fibrosis, which are also the main manifestations of  
110 SS.[[9-21](#)]

111

112 Bank et al. infiltrated decanted fat only in order to treat RP and obtained extraordinary results  
113 in terms of improving pain and RP.[22] Del Papa et al. centrifuged fat and injected the  
114 intermediate layer into patients with SS and active digital ulcers that were resistant to  
115 conventional treatment.[14, 15] Subsequently, Del Papa et al. reported on the same technique  
116 in a controlled study in 2019. The digital ulcers healed after a mean period of 8 weeks with the  
117 reduction of pain and formation of new capillaries.[23]

118 Granel et al. administered the ADSVF to 12 patients who predominantly had limited cutaneous  
119 SS with no severe involvement of the internal organs. Subsequently, they reported  
120 improvements in pain and the frequency and intensity of RP; the healing of digital ulcers that  
121 were resistant to conventional treatments; improved strength, movement, and Cochin  
122 functional scale scores; and a decrease in the digital circumference.[24] Further, these results  
123 were reported to persist for 12, 22, and 30 months postoperatively with additional  
124 improvements in nail appearance and health based on improved Scleroderma Health  
125 Assessment Questionnaire scores, the ability to participate in household activities, and the  
126 approval of the procedure by the patients themselves.[21, 25, 26] Del Papa et al. and Granel et  
127 al. reported that the treatment was safe and well tolerated.[14, 24]

128 Lipoatrophy may develop in patients with SS due to the loss of adipocytes and defective stem  
129 cell function.[13, 27] Thus, there is a good possibility that the hands of patients with SS could be  
130 treated with ADSVF plus fat grafts with the from proximal sites, such as the abdominal wall. For  
131 these reasons and because there has been only one controlled trial, we designed this controlled

132 clinical trial with the aim of evaluating the safety, reproducibility, and clinical effects of treating  
133 the hands of patients affected with SS with the administration ADSVF plus fat micrografts.

134

## 135 **METHODS**

136 This open-label, monocentric, randomized controlled pilot study was approved by the  
137 Institutional Review Committee with the reference, SCI-1505-15/15-1, and was registered with  
138 ClinicalTrials.gov under the identifier, NCT04387825. We used a random number table to assign  
139 patients into different groups. Informed consent to participate in this study was obtained from  
140 all the participants. Both the experimental and control groups contained 10 patients each who  
141 were diagnosed with SS according to the criteria of the American College of Rheumatology and  
142 LeRoy-Medsger criteria. All the patients were aged > 18 years and had BMIs > 18 kg/m<sup>2</sup>. All the  
143 patients had undergone stable vasoactive and immunosuppressive therapies for at least 1  
144 month before enrollment in the study, and these treatments were continued unchanged  
145 throughout the study period. The exclusion criteria were infected digital ulcers, comorbidities  
146 that could affect hand function, alcoholism, and/or drug abuse. It was decided that the  
147 treatment would be administered to the most affected hand of the patients, which was the  
148 right hand in the entire experimental group. ADSVF and fat micrografts were administered in  
149 the experimental group. The evolution of the disease and the medical therapy effects were  
150 observed in the control group. Demographic and serologic data were recorded as well as

151 disease severity according to the Medsger severity scale. The evaluated variables and follow-up  
 152 times are presented in Table 1.

 154

155

156 Data regarding the presence of complications, such as compartment syndrome and/or infection,  
 157 in both the donor site and treated hand were recorded daily for 1 week.

158 Rheumatological data were retrieved by the rheumatologist group, and medical interns were  
159 trained to allocated patients and collect the other data.

#### 160 **Tissue collection and ADSVF preparation**

161  
162 Fat grafts were obtained by liposuction under local anesthesia. Briefly, the periumbilical region  
163 (9 patients) or posterior thigh (1 patient) was infiltrated with 500 ml of Klein's formula.  
164 Liposuction was performed with a 20-ml syringe and 3-mm diameter blunt cannula with 2-mm  
165 openings. A total of 100 ml of fat was harvested, from which 60 ml was transferred to sterile  
166 flask containing Hank's balanced saline solution with 5% albumin and was immediately  
167 transported to the laboratory. The adipose tissue was decanted for 10 minutes in a laminar flow  
168 cabinet for fraction separation. The upper fraction comprised disrupted adipocytes (oil), and the  
169 lower fraction was a fluid portion containing the anesthetic solution, erythrocytes, and dead  
170 cells. These both fractions were removed. The middle fraction was washed twice in phosphate-  
171 buffered saline (PBS) (Gibco, Thermo Fisher Scientific, Waltham, MA, USA) and subsequently  
172 incubated for 20 minutes in a type II collagenase solution (Sigma, St. Louis, MO, USA) in PBS at a  
173 concentration of 2 mg/ml of lipoaspirate. This was followed by addition of  
174 ethylenediaminetetraacetic acid (Sigma) in PBS. To separate the ADSVF from the floating  
175 adipocytes, this digested tissue was centrifuged at  $800 \times g$  for 10 minutes. The compacted cells  
176 were resuspended in 3 ml of PBS and filtered through a 100- $\mu$ m mesh cell strainer (Corning Inc.,  
177 Corning, NY, USA). A 10  $\mu$ l aliquot was obtained from each patient to characterize the ADSVF  
178 cellular identity by flow cytometric assays. After the fat was processed, 2 ml of the ADSVF was

179 transferred back to the operating room for the autologous transplantation procedure. Another  
180 1 ml sample was used for cell quantification, viability determination, and cell culturing to  
181 determine the adipocyte differentiation capacity (Figure 1).

182  
183 The cells were seeded in 6-well culture plates in Dulbecco's modified Eagle's medium and were  
184 supplemented with fetal bovine serum and antibiotic/antifungal agents. Upon reaching 90%  
185 confluence, the cells were differentiated into mature adipocytes using a differentiation cocktail  
186 (2.5  $\mu$ M dexamethasone, 0.5 mM 3-isobutyl-1-methylxanthine, 10  $\mu$ g/ml insulin). As a control, a  
187 plate containing cells in the culture medium was left without adipogenic stimulation. After 20  
188 days of differentiation, the cells were stained with oil red to assess fat accumulation (mature  
189 adipocyte phenotype), and the fat content in each culture was quantified by spectrophotometry  
190 (Figure 1 A-F).

191  
192 **ADSVF administration into the hand**  
193 A nerve blockade was induced in the median, ulnar, and radial nerves at the wrist level using 2%  
194 lidocaine without epinephrine. Subsequently, 40 ml of fat was mixed with 2 ml of the ADSVF  
195 and was transferred to 1-ml and 3-ml syringes. Using a 19-gauge blunt cannula (0.8 mm), 1.5 ml  
196 was administered along each radial and ulnar neurovascular digital pedicle through small radial  
197 and ulnar skin incisions at the level of the interphalangeal and metacarpophalangeal joints.  
198 Additionally, 3 ml was administered to each side of the metacarpal trapezius joint, together with

199 the subcutaneous distribution of 10 ml throughout the palm of the hand and even distribution  
200 of 10 ml in the back of the hand. The study was carried out from October 2018 to May 2019.

201

## 202 **Statistical analysis**

203 Continuous variables are expressed as median with 95% confidence interval. Dichotomous  
204 variables are expressed as frequency and percentage. Categorical or dichotomous variables  
205 were analyzed with Fisher's exact test. The differences between before and after the  
206 intervention were analyzed with the Wilcoxon range test, and the differences between the  
207 control and experimental groups at 0 days and 168 days were analyzed with the Mann–  
208 Whitney U test. The analysis was enhanced to determine the interaction between time (0/168  
209 days) and treatment (control/experimental) with analysis of variance for repeated measures,  
210 and logarithmic transformation was performed before such analysis. A P value of <0.05 was  
211 considered statistically significant of a tail. The data were analyzed using SPSS for Windows,  
212 version 24.00 (IBM Corp., Armonk, NY, USA) and GraphPad Prism software version 7 (GraphPad  
213 Software, San Diego, CA, USA).

## 214 **RESULTS**

215 Demographic, serological (antibodies), and disease severity-related data are presented in Table  
216 2.

P<sup>1</sup> Statistical significance analyzed Fisher's exact test.

\*Statistical significance analyzed with Mann-Whitney U test

220

221 The baseline characteristics were similar between the two patient groups. All the patients

222 presented with moderately intense vascular and joint conditions. Some patients exhibited  
223 severe internal organ involvement. One control group patient withdrew from the study due to  
224 personal problems.

225 The total viable nucleated cell numbers and cellular characteristics of the ADSVF are outlined in  
226 [Additional file 1 Table A.](#)

227 The abilities to adhere to plastic and differentiate to adipocytes are presented in Figure 1. G-I  
228 greater amount of fat content was found in cell cultures induced toward adipocyte  
229 differentiation than in control cultures ( $p = 0.0001$ ).

230 At the completion of ADSVF administration, the digits did not exhibit capillary filling, but  
231 circulation was reestablished after 2 h. There were no adverse effects. Digital oximetry (SpO<sub>2</sub>),  
232 digital total active motion, thumb opposition, hand function, health status and disability index,  
233 and vascular density of the nail bed, were similar in the two groups at the study's end.

234 The pain score increased from 4.6 to 7.5 in the first week, gradually decreased to reach the  
235 basal value at day 7, and subsequently began to decrease further. Significant improvements  
236 were observed in pain and quality of life score (Short Form 36) in the experimental group at the  
237 study's end. The frequency, intensity and duration of RP have significant improvement in both  
238 groups at 168 days, but were more important in the experimental group. The skin affection of  
239 the hand improved significantly in the control group. However, when the results at 168 days

240 were statistically compared between the groups, only pain exhibited a significant improvement  
 241 ( $p = 0.02$ ) (Table 3 and [Additional file 2 Table B](#)).

Table 3. Results in control and experimental groups

Concept	Group	Day 0	Day 168	P <sup>1</sup>	P <sup>2</sup>
Pain	Control	4.00(2.64,6.16)	2.00(1.51,6.04)	0.91	
	Experimental	5.00(3.08,6.12)	0.00(0.00,2.95)*	<b>0.006*</b>	<b>0.02*</b>

	Experimental	2.00(1.50,2.10)	0.50(0.10,1.10)	<b>0.006*</b>	0.60
Raynaud Phenomenon <i>duration in minutes</i>	Control	17.5(2.12,54.4)	0.00(0.00,10.3)	<b>0.02*</b>	
	Experimental	12.5(6.55,35.6)	0.00(0.00,6.82)	<b>0.005*</b>	0.14
Skin affection of the hand	Control	6.50(2.32,15.8))	5.50(1.42,12.9)	<b>0.05*</b>	
	Experimental	15.0(6.84,17.7)	15.5(6.36,16.6)	0.07	0.19

The sample size of the control group n=9, experimental group n=10; Data are presented as median (95% confidence intervals).

P<sup>1</sup>= Analyze the differences within groups between baseline and final results. Wilcoxon signed-rank test was used.

\*P<0.05, U de Mann-Whitney analyze the differences between groups.

P<sup>2</sup>= These data were log-transformed before statistical analyses was ANOVA for repeated measures to determine the time x group interaction.

242  
 243

244 The digital ulcers in the experimental group healed within 28 days, while those in the control  
 245 group healed within 84 days. During the follow-up period, ulcer recurrence was observed in one

246 experimental group patient compared with in three control group patients. These results were  
247 statistically significant (Table 4).

248

Table 4. Ischemic Digital Ulcers in Sclerosis Systemic

Group	Day 0	Day 28	Day 56	Day 84	Day 112	Day 140	Day 168
Experimental (n 10)	3	0	0	0	0	1	0
Control (n 9)	4	4	2	1	2	2	6
<i>p</i> value*	0.50	0.03	0.21	0.47	0.248	0.45	0.003

\*statistical analysis was performed with the exact fisher test

249

250 Clinically, the treated hands of the experimental group patients exhibited larger volumes,  
251 warmer temperatures, and faster capillary filling than the contralateral hands of the same  
252 patients (Figure 2 and Video 1).

253

254 Both groups exhibited late capillaroscopic patterns. There was no significant change in the  
255 number of nailfold capillary loops between the groups at the study's end. One experimental  
256 group patient exhibited an improved capillaroscopic pattern changing from late to early, while  
257 one control group patient exhibited a worsened capillaroscopic pattern changing from early to  
258 late.

259

## 260 **DISCUSSION**

261

262 The application of decanted fat,[\[22\]](#) centrifuged fat,[\[14\]](#) and the ADSVF,[\[15, 25, 28\]](#) has  
263 consistently and significantly improved pain, RP, and the healing of digital ulcers in the hands of

264 patients with SS, thereby improving their quality of life. Other inconsistently observed benefits,  
265 such as decreased digital circumferences, improvements in digital mobility and strength,  
266 improvements in the formation of new subungual capillaries, and improvements in function  
267 based on Cochin scale scores, have also been reported.[\[14, 15, 23\]](#)

268  
269 However, previous studies have been uncontrolled with a short follow-up period of 6  
270 months.[\[14, 15\]](#) There has been only one controlled study that involved the use of decanted  
271 grafts.[\[23\]](#) Within 8 weeks, digital ulcer healing was observed in 92% of the experimental group  
272 patients compared to in 7.7% of the control group patients. Furthermore, at 20 weeks, pain  
273 levels were decreased, and the number of unguual capillaries was increased in the experimental  
274 group compared with in the control group.[\[23\]](#)

275  
276 The present controlled study with a 6-month follow-up period included patients with diffuse  
277 and limited SS as well as moderate vascular and articular involvement, including some with  
278 severe internal organ involvement. The results observed in the experimental group were similar  
279 to those reported in uncontrolled studies. There were statistically significant improvements in  
280 pain, , digital ulcer healing and SF-36 scores in the experimental group. However, when the  
281 variables were compared with those of the control group, only the improvement in pain was  
282 statistically significant. Clinical important improvements were observed in quality of life, as well  
283 as in intensity, duration and frequency of RP. In the experimental group. We believe that this  
284 may be related to the sample size and suggest that it is necessary to conduct further studies

285 with larger numbers of patients. This study was carried out in mid-October with the final  
286 evaluation conducted in May when the environmental temperature was warmer.

287  
288 We are convinced that fat micrografts can be enriched with the ADSVF in order to acquire the  
289 widely known volumetric effect of lipo-injections as well as the benefits of tissue regeneration  
290 produced by the ADSVF. This mixture has already been suggested by Magalon.[25] In our study,  
291 the volume infiltrated into each digit was 3 ml. This cellular mixture was administered adjacent  
292 to each neurovascular digital pedicle, rather than only into the digital web spaces based on the  
293 procedure performed by Bank.[22] Our patients presented with moderately intense vascular  
294 and joint conditions and had Cochin scores ranging up to 63. In patients with Cochin scores  
295 above 30, the fingers exhibit structured joint stiffness and significant sclerodactyly. Even in  
296 these patients, it was possible to administer the cell suspension without causing adverse effects,  
297 such as ischemia or compartment syndrome, and without the need for a relaxing incision, as  
298 pointed out by Del Papa.[14, 23]

299 Unlike the conclusion of Malagon,[25] we consider that fat micrografts enriched with the ADSVF  
300 are useful for the treatment of mild, moderate, and severe injuries in patients with ischemic  
301 hands resulting from SS, including in those with structured joint stiffness. Although no  
302 improvements were observed in movement in the present study, additional clinically relevant  
303 benefits, such as decreased pain and improved RP, digital ulcer healing were observed.

304

305 The site and technique used for acquiring the lipoaspirate affect the quality of the ADSVF in  
306 terms of its use for regenerative treatment.[29] Liposuction collection sites have been reported  
307 in the knee, hip, femoral region, and abdomen.[14, 24, 25] In our study, fat grafts were mainly  
308 obtained from the periumbilical region that is suggested to be the optimal site. Similar  
309 techniques have been used for fat acquisition in all studies, including the present work.

310  
311 Granel et al. processed the ADSVF with a Celution 800/CRS system.[24] Malagon et al. noted  
312 that the process requires an evaluation in a cell biology laboratory.[25] In this study, we isolated  
313 the ADSVF in a cell biology laboratory. The mean number of viable cells in the ADSVF that we  
314 isolated was  $228.05 \times 10^6 \pm 10.8$  compared with  $50.5 \pm 23.8$  (16.7.92.6) in previous studies.[24]  
315 Even when there was a larger number of cells in the ADSVF, in addition to those in the fat  
316 micrografts, it did not affect our final results.

317  
318 The techniques performed by the Granel and Magalon group for the characterization and  
319 determination of the proportion of the ASCs contained in the ADSVF were consistent with the  
320 requirements of the International Federation for Adipose Therapeutics and Science and the  
321 International Society for Cellular Therapy and with the Bourin report.[24, 25, 30] In the present  
322 study, cell characterization was performed using the following markers: CD34, CD44, CD45,  
323 CD73, CD90, CD105, and human leukocyte antigen (HLA)-DR. Their values, together with their  
324 adherence to plastic and differentiation toward adipocytes in the laboratory, indicate that the  
325 cellular mixture in the ADSVF from our patients, which included mesenchymal stromal cells,

326 endothelial progenitor cells, pericytes, hematopoietic, and immune cells, is similar to those  
327 reported previously.[[20](#), [24](#), [25](#), [30](#)] Therefore, the obtained results may be explained by the  
328 local angiogenic, anti-inflammatory, antifibrotic, immunomodulatory, and regenerative  
329 properties of the autologous injected ASCs. It has been demonstrated that the vascular or  
330 regenerative properties of the ADSVF are not compromised by SS.[20] Although it is assumed  
331 that the administration of the ADSVF may have some systemic effects, the involvement of  
332 internal organs did not improve or worsen in association with SS in our patients.

333  
334 The treated hands of the experimental group patients exhibited a clinically greater volume than  
335 the contralateral hands in the same group and hands of the control group patients. This greater  
336 volume could prevent the recurrence of ulcers on the bony prominences.

337  
338 Our study has proven that when combined with conventional medical therapies, the  
339 administration of fat micrografts enriched with the ADSVF into the hands of patients with SS can  
340 significantly improve pain. Studies with larger numbers of patients are necessary in order to  
341 confirm that this method can improve digital ulcer healing, RP, digital perfusion, the vascular  
342 density of the nail bed, and the function of the hand.

343  
344 Based on the aforementioned findings, the regenerative medicinal benefits of the ADSVF are an  
345 essential aid for rheumatologists and plastic surgeons before or during the treatment of hand d  
346 eformities in patients with SS.

347 **CONCLUSION**

348 The administration of fat micrografts enriched with the ADSVF is a reproducible, safe, and well-  
349 tolerated treatment option for the hands of patients with SS. This procedure offers the  
350 advantages of the volumetric effect of fat and its regenerative properties. Decreased pain levels  
351 and increased healing of digital ulcers, were observed in our patients with SS as well as a  
352 tendency toward improvements in RP, and quality of life. Although it is necessary to conduct  
353 further studies with larger numbers of patients, we conclude that this treatment is safe and can  
354 be administered as a preventive strategy to avoid the progression of hand deformities in  
355 patients with SS.

## 368 **DECLARATIONS**

### 369 **Ethics approval and consent to participate**

370 This research was approved by Institutional Review Committee and The Research Ethical  
371 Committee of Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, with the  
372 reference, SCI-1505-15/15-1.

373 Informed consent to participate in the study was approved by the same committees and was  
374 obtained from all the participants.

### 375 **Consent for publication**

376 The patients involved in this research in both groups have signed our institutional consent form  
377

### 378 **Availability of data and materials**

379 All data generated or analyzed during this study are included in this published article and its  
380 supplementary information files as: [Additional File 1 Table A](#), [Additional File 2 Table B](#),  
381 [Additional File 3 Statistics](#), and [Additional File 4 Patient and Public Involvement 1](#)

### 382 **Competing interests**

383 The authors declare that they have no competing interests

384

### 385 **Funding**

386 Consejo Nacional de Ciencia y Tecnologia (CONACYT) funding this research, with the Sectorial  
387 Research Fund in Health and Social Security I0000/739/2017.

388

389 **Author's contributions:**

390 MI: Performed the protocol and the procedure, draft of the manuscript; critically revising the  
391 manuscript, data interpretation and discussion of results.

392 ITV: Isolation of Adipose Derived Stromal Vascular Fraction, and revision of the manuscript.

393 PBG: Collaboration in the procedure and postoperative control.

394 TSRR: Performed the protocol and selection of candidate patients.

395 EATA: Isolation of Adipose Derived Stromal Vascular Fraction, and revision of the manuscript.

396 ARTP: Performed the protocol and analysis of the results.

397 AZD: Performed cellular characterization.

398 MGC: performed the statistical analysis

399 AMHC: Performed the protocol, enroll patients and obtain informed consent.

400

401 **Acknowledgements**

402 The authors thank to Claudia Chavez-Muñoz, MD, for her scientific support, and the Consejo  
403 Nacional de Ciencia y Tecnologia (CONACYT) for their funding support.

#### 524 FIGURE LEGEND

525 Figure 1. Flow chart of the methodology. (A) Fat grafts are obtained by abdominal liposuction.  
526 (B) A 60 ml volume is sent to the laboratory. (C) The enzymatic digestion of fat is performed by a  
527 collagenase separation method. (D) The initial adipose-derived stromal vascular fraction  
528 (ADSVF) is divided into two samples. (E) The first is a 1 ml sample for the characterization and  
529 control of the cell culture. (F) The second is a 2 ml sample that is reserved for administration to  
530 the patient in a lipoaspirate mixture by infiltration into the hand. The differentiation process is  
531 depicted in the last row. Differentiation. (G) Control culture without adipogenic stimulation  
532 stained with oil red (OR) at day 20. (H) Culture with adipogenic stimulation stained with OR on  
533 day 20. (I) Spectrophotometric analysis of the two groups depicted in a graphic. There was *a*  
534 *higher OR absorption level in the differentiated group* ( $p = 0.0001$ ).

535

536 Figure 2. Clinical results. (A, B) Patient 1, female with age range 56-60 y/o. The right hand was  
537 injected with micrografts enriched with the adipose-derived stromal vascular fraction. It  
538 exhibited a higher volume and was warmer than the left hand. (C) Patient 2, female with age  
539 range 31-35 y/o. Clinical status before the treatment. The hand presented with dermo-  
540 epidermal abrasions and digital ulcers. (D) The same patient with healing digital ulcers.
