## 13 **Abstract**

14 The gold standard for SARS-CoV-2 infection diagnosis is RT-PCR from nasopharyngeal specimen  
15 (NPS). Its collection involves a close contact between patients and healthcare workers requiring a  
16 significant amount of workforce and putting them at risk of infection. We evaluated self-collection  
17 of alternative specimens and compared their sensitivity and Ct values to NPS. We visited acute  
18 COVID-19 outpatients to collect concomitant nasopharyngeal and gargle specimens and had  
19 patients self-collect a gargle and either sputum or spit specimens on the next morning.

20 We included 40 patients and collected 40 concomitant nasopharyngeal and gargle specimens, as  
21 well as 40 gargle, 22 spit and 16 sputum specimens on the next day, as 2 patients could not  
22 produce sputum.

**NOTE:** This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.

23 All specimens were as sensitive as NPS. Gargle specimens had a sensitivity of 0.97 (CI 95% 0.92-  
24 1,00), whether collected concomitantly to NPS or on the next morning. Next morning spit and  
25 sputum specimens showed a sensitivity of 1.00 CI (95% 1.00-1.00) and 0.94 (CI 95% 0.87-1.00),  
26 respectively. The gargle specimens had a significantly higher mean cycle threshold (Ct) values,  
27 29.89 (SD 4.63) (p-value <0.001) and 29.25 (SD 3.99) (p-value <0.001) when collected  
28 concomitantly and on the next morning compared to NPS (22.07, SD 4.63). Ct value obtained with  
29 spit (23.51, SD 4.57, p-value 0.11) and sputum (25.82, SD 9.21, p-value 0.28) specimens were close  
30 to NPS.

31 All alternative specimen collection methods were as sensitive as NPS, but spit collection appeared  
32 more promising, with a low Ct value and ease of collection. Our findings warrant further  
33 investigation.

34

## 35 **Introduction**

36 In December 2019, SARS-CoV-2 emerged from the Chinese city of Wuhan (1). The disease spread  
37 into countries outside China and was declared a global pandemic in March 2020 (2). Within a year,  
38 more than 115 million COVID-19 cases were confirmed, including two and a half million deaths  
39 (3).

40 The SARS-CoV-2 pandemic control relies on a test-trace-isolate strategy with early diagnosis and  
41 isolation of infected individuals and identification of their contacts (4) which has led to an initial  
42 shortage of personal protective and sampling equipment, as well as increasing healthcare workers'  
43 workload (6,7). Alone in Finland, a country with approximately 5 500 000 inhabitants, by the 20<sup>th</sup>

44 of March 2021 over 3 700 000 tests, of which 145 000 during the first week of March 2021, were  
45 conducted and analyzed nationwide during the COVID-19 pandemic (5,6).

46 Collection of nasopharyngeal specimen (NPS) is the gold standard for SARS-CoV-2 infection  
47 diagnosis (7). However, it is an unpleasant procedure requiring a close contact with HCW with a  
48 risk of discomfort and in worst cases, epistaxis for the patient, and infections exposure for the  
49 HCW (8,9). The use of an alternative specimen collection method could increase specimen  
50 collection and testing capacities as well as decrease HCWs' workload and risk for infection (8).  
51 There has been several studies evaluating alternative specimen collection methods but none of  
52 the specimen collection methods have yet superseded NPS (10–13), even though one Finnish  
53 private healthcare provider now offers asymptomatic patients the possibility to self-collect a  
54 gargle specimen as an alternative to NPS (14).

55 We evaluated and compared three alternative specimen collection methods that would not  
56 require close contact to a HCW and compared their sensitivity and Ct values to NPS.

57

## 58 **Materials and methods**

59 We contacted confirmed COVID-19 outpatients who had been diagnosed with SARS-CoV-2  
60 infection by RT-PCR (reverse transcription polymerase chain reaction) on NPS a few days earlier.  
61 Children under 2 years old were not eligible for participation. After calling the patient for  
62 recruitment, we visited them on the same and following day.

63 During the first home visit, we gathered informed consent, gave participants a link to an online  
64 symptom- questionnaire and collected a NPS and gargle specimen (gargle 1). We also gave them  
65 instructions and containers for collection of gargle (gargle 2) and, depending on the recruitment

66 week, sputum or spit specimen on the next morning. On the following day, the patients collected  
67 themselves the second gargle (gargle 2) and either spit or sputum specimens. The next day the  
68 self-collected specimens were collected. The timeline of the study is presented in Figure 1.

69 All alternative specimens were collected into a 70 ml plastic container. To collect the gargle  
70 specimens, the patients were asked to have sip of water, and gargle it for 5-20 seconds before  
71 spitting it in the container. For spit collection, the patients were asked to spit continuously into the  
72 container until filled to half its volume, and with sputum specimen they were asked to cough  
73 sputum deep from their lungs and then spit it into the container. Both the spit and sputum  
74 specimens were advised to be collected in the morning before the patients ate, drunk or brushed  
75 their teeth.

76 All specimens were transported at room temperature and analyzed on the same day in Expert  
77 Microbiology unit at the Finnish Institute for Health and Welfare (THL).

78 The Finnish communicable diseases law and the law on the duties of THL allows the  
79 implementation of this noninvasive research without seeking further ethical approval (THL-laki 5 e  
80 §; Tartuntatautilaki 7 § and 23 §).

### 81 ***Laboratory methods***

82 RNA extraction from samples was performed using Chemagic Viral300 DNA/RNA Kit H96 (PerkinElmer)  
83 according to the manufacturer's instructions. A sample volume 300 µl and an elution volume 50 µl  
84 were used. Highly viscose gargle samples were vortexed with 1 ml PBS before taking 300 µl for  
85 RNA extraction. Real time RT PCR was performed using qScript™ XLT One-Step RT-qPCR  
86 ToughMix® (Quantabio). SARS-CoV-2 was detected using the E (envelope) gene real-time RT-PCR  
87 assay. Primers and probes were based on the Corman E gene premier/probe set(15). The thermal

88 profile for PCR was 55°C for 20 min and 95°C for 3 min, followed by 45 cycles at 95°C 15 s and  
89 58 °C 1 min using CFX thermal cycler (BioRad).

## 90 **Statistical analysis**

91 We used NPS RT-PCR test results as reference method and Ct values as surrogates for viral load  
92 analysis. We performed paired t-test or Wilcoxon signed-rank test to compare the measured Ct  
93 values between nasopharyngeal and gargle, and between nasopharyngeal and sputum/spit  
94 specimens. Standard methods were used to calculate sensitivity and specificity of the other  
95 diagnostic tests (index tests) from saliva- and sputum/spit specimens. Exact McNemar’s test was  
96 used to assess the differences in sensitivity and specificity.

97 We calculated Cohen’s kappa coefficient to evaluate the agreement between the reference and  
98 the index tests. Area under a receiver operating characteristic curve (AUC) and 95% CI were  
99 reported. Because of the imperfect reference test, latent class analysis was used as a correction  
100 method to adjust the estimated sensitivity and specificity of the index tests based on the existing  
101 sensitivity and specificity of the reference test. Model selection was based on Bayesian  
102 information criterion (BIC). Data analysis was performed using R software (version. 3.6.0).

103

## 104 **Results**

105 We enrolled 40 patients with a mean age of 38.7 years old (SD: 12.6) including 21 (53%) females.  
106 Enrolment was done as soon as they received the positive testing results, either one day (n=27/40,  
107 67.5%) or two days (n=13/40, 32.5%) after they had been NPS sampled for COVID-19 diagnosis.  
108 Thirty-one patients had been symptomatic since disease onset (supplementary table 1) with most  
109 prevalent symptoms being fatigue (86%), headache (81%) and cough (79%). At the time of

110 specimen collection, only 24 patients were symptomatic with the most prevalent being cough  
111 (44%), anosmia (42%) and headache (40%).

112 We collected 40 concomitant nasopharyngeal and gargle specimens on recruitment day, as well as  
113 40 next morning gargle specimens. Out of 22 patients assigned to the spit specimen collection  
114 group, all of them gave back specimens, while out of 18 patients assigned to the sputum group,  
115 two patients could not produce sputum.

116 All specimens were generally as sensitive as NPS to diagnose SARS-CoV-2 infection in our study  
117 population. The spit specimen showed the highest sensitivity (sensitivity 1.00 CI 95 % 1.00-1.00),  
118 followed by gargle specimens, regardless of when they were collected: 0.97 (CI 95 % 0.92-1.00).  
119 The sputum specimen had the lowest sensitivity (0.94 CI 95 % 0.87-1.00).

120 We compared Ct values obtained from alternative specimens to NPS (Table 2). NPS had the lowest  
121 Ct value (22.07, SD 4.63), although it was not significantly lower compared to sputum (25.82, SD  
122 9.21), (p-value 0.28) and spit (23.51, SD 4.57), (p-value 0.11) specimens. Both gargle specimens  
123 had statistically significantly higher Ct values, compared to NPS (Table 2).

124 All patients' different specimens' results are presented in supplementary figures 1-4.

125

## 126 **Discussion**

127 We evaluated self-collection of alternative specimens: gargle, spit and sputum and compared their  
128 sensitivity and Ct values to NPS specimens as alternative methods for SARS-CoV-2 infection  
129 diagnosis. All specimen collection methods were as sensitive as NPS, with sensitivities exceeding  
130 90 %. In comparison with NPS, the gargle specimens had higher Ct values, likely due to dilution by  
131 gargling water. Therefore in milder cases with low viral load, it might not be as sensitive as NPS.

132 Spit and sputum specimens collected on the following day had a higher though not significantly  
133 different Ct value compared to NPS, however, sputum appeared more challenging to collect in  
134 patients with milder symptoms. Hence, spit would appear as the most suitable alternative  
135 specimen to NPS for SARS-CoV-2 infection diagnosis.

136 Since the beginning of the COVID-19 pandemic, several studies or meta-analysis have investigated  
137 the potential use of saliva specimen for SARS-CoV-2 infection diagnosis among both symptomatic  
138 (8,9,11,16–21) and asymptomatic patients (8,9,11,16–18,21,22). ECDC and CDC have approved  
139 the use of saliva or sputum as a diagnostic specimen for COVID-19 for patients with a productive  
140 cough (23,24).

141 There has been mixed results considering difference in Ct levels between NPS and saliva  
142 specimens (11,19,20,22). These inconclusive results can be caused by various factors: morning  
143 saliva might have higher viral load compared to the rest of the day (18), levels of SARS-CoV-2 virus  
144 in saliva correlate to COVID-19 symptoms severity (25). Additionally, early-morning posterior  
145 oropharyngeal spitting technique has been considered to have higher sensitivity for SARS-CoV-2  
146 infection diagnosis compared to NPS (8).

147 Previously, gargle specimens have also been estimated sensitive for SARS-CoV-2 infection  
148 diagnosis compared to NPS including 50 inpatients (26) and outpatients (10,27) with confirmed  
149 COVID-19. Ct values of gargle specimens were higher than in NPS in these three studies including  
150 one with 19 620 outpatients which is in line with findings in our study (10,26,27). Interestingly  
151 Goldfard et al, when analyzing 40 COVID-19 outpatients concluded that gargle specimens had  
152 higher sensitivity compared to saliva specimens (97.5 % CI 86.8-99.9 % compared to 78.8 CI 95 %  
153 61.0-91.0 %) which is inconsistent with our results, although saliva collection methods were similar  
154 (10).

155 Levican et al and Malczynski et al showed that diagnostic results and Ct values were comparable  
156 between sputum and nasopharyngeal tests during the first ten days after COVID-19 diagnosis in  
157 study population of 82 and 50 hospitalized patients, respectively (28,29). The result was also  
158 consistent with this study.

159 Alternative specimens' collection main benefit compared to NPS would be to avoid close contact  
160 with a HCW, to allow participants to collect the specimen themselves and to avoid an unpleasant  
161 procedure. Overall, it would also increase the willingness to apply for SARS-CoV-2 testing and  
162 allocation of current resources in HCWs.

163 The main limitations of our work are that we did not analyse whether delayed transport or  
164 extended storage before analysis could hamper sensitivity as all samples were transported and  
165 processed on the very same day and our low sample size (40 participants in total), however we  
166 conducted this study as an exploratory assessment of alternative specimen collection. We focused  
167 on patients with the most common clinical picture of COVID-19: mild symptoms, as they are the  
168 ones that would most benefit from non-invasive alternative specimen collection. An additional  
169 strength was that all samples were collected within 1-2 days after diagnosis, while patients were  
170 still at the acute phase of the disease.

171

## 172 **Conclusion**

173 Among gargle, spit and sputum specimens, morning collection of approximately 30 mL of spit  
174 before any food and water intake or teeth brushing appeared to be the most suitable alternative  
175 specimen collection method with a Ct-value as low as obtained with NPS and ease of collection for  
176 patients with mild symptoms. Our findings were promising but warrant further investigations with

177 larger study population. We will consider offering the possibility to patients with mild symptoms  
178 seeking diagnosis in a pilot testing centre, the possibility to enroll in a study assessing whether in  
179 general population, spit collected on the next morning has the same performance as in our  
180 exploratory sample. If so, in the long run, we could offer patients with mild symptoms to choose  
181 between at home self-collection of spit versus nasopharyngeal specimen collection at a testing  
182 centre. Not only would it decrease discomfort, but also decrease HCWs' exposure and burden.

### 183 **Acknowledgements**

184 The authors thank Helsinki city and Helsinki city's Epidemiological Unit for sharing data of the  
185 COVID-19 patients. We are also grateful to THL Virology laboratory staff who analyzed the  
186 specimens among other works.

288 **Figure 1.** Timeline of the study. NPS =Nasopharyngeal specimen.

	NPS		Sensitivity (95% CI)	Specificity (95% CI)	Sensitivity (corrected)	Specificity (corrected)	Cohen's kappa (95% CI)	AUC (95% CI)
	+	-						
Gargle 1	+	37	0.97 (0.92, 1.00)	0.50 (0.00, 1.00)	0.97 (0.02, 1.00)	0.50 (0.00, 1.00)	0.47 (-0.15, 1.00)	0.74 (0.47,1.00)
	-	1						
Gargle 2	+	37	0.97 (0.92, 1.00)	0.50 (0.00, 1.00)	1.00 (1.00, 1.00)	1.00 (0.87, 1.00)	0.47 (-0.15, 1.00)	0.74 (0.47,1.00)
	-	1						
Sputum	+	13	0.94 (0.83, 1.00)	0	-	-	-0.09 (-0.22, 0.04)	0.54 (0.50, 0.61)
	-	2						
Spit	+	21	1.00 (1.00, 1.00)	1.00 (1.00, 1.00)	-	-	1.00 (1.00, 1.00)	1 (1,1)
	-	0						

289 **Table 1.** Sensitivity and specificity of tested sampling methods

Sample	n	Mean (SD)/	p-value
Nasopharyngeal	40	22.07 (4.63)	Ref
Gargle 1	40	29.89 (4.34)	< 0.001 <sup>a</sup>
Gargle 2	40	29.25 (3.99)	< 0.001 <sup>a</sup>
Sputum	16	25.82 (9.21)	0.28 <sup>a</sup>
Spit	22	23.51 (4.57)	0.11 <sup>a</sup>

<sup>a</sup> Paired t-test  
<sup>b</sup> Wilcoxon signed-rank test

290 **Table 2:** Comparison of Ct-values obtained with alternative samples to nasopharyngeal samples.

## Instructions for sampling gargle, spit and sputum

### Gargle sample

- Have a sip of water (1/4 of a glass)
- Gargle
- Spit is back in the container
- Close the container
- Seal it in the zypbag

### Spit sample

- Upon waking up, avoid food, water and brushing your teeth until the spit sample is collected
- Repeatedly spit into the container until it is half full with liquid (excluding bubbles)
- Securely close the container
- Store at room temperature

### Sputum sample

- Lean forward and cough hard to get tough mucus from the lower airways.
- Approximately tablespoon of mucus is enough to sample
- Close the container and put the container back to the zypbag seal it carefully.
- Store the container in the refrigerator until the samples are retrieved.
