Supplemental Figures

Figure S1. Predicted clearance by weight for selected ages for *UGT1A4* model. Plausible weight ranges for each age group are: 6 months (5 - 12 kg), 12 months (6 - 13 kg), 24 months (8 - 16 kg), 48 months (12 - 22 kg), 72 months (15 - 28 kg), 90 months (18 - 35 kg), 120 months (23 - 50 kg). Overlapping lines between different age categories represent weights that are plausible for multiple ages.

Calculation of genotype effect in terms of equivalent change in weight

From the final model average $CL = \theta_1 \times \left(\frac{WT_i}{70}\right)^{0.75} \times \exp(\theta_5 \times AGE_i + \theta_6)$ for a subject with a *UGT2B10* variant. A subject with the equivalent age, no variants, and weight reduced by factor Δ will have average $CL = \theta_1 \times \left(\frac{WT_i \times \Delta}{70}\right)^{0.75} \times \exp(\theta_5 \times AGE_i)$. Setting these two equations equal and solving for Δ will give the proportional weight change that has the same impact on CL as having a genotype variant

$$\theta_1 \times \left(\frac{WT_i}{70}\right)^{0.75} \times \exp(\theta_5 \times AGE_i + \theta_6) = \theta_1 \times \left(\frac{WT_i \times \Delta}{70}\right)^{0.75} \times \exp(\theta_5 \times AGE_i)$$

$$\left(\frac{WT_i}{70}\right)^{0.75} \times \exp(\theta_5 \times AGE_i) \times \exp(\theta_6) = \left(\frac{WT_i}{70}\right)^{0.75} \times \Delta^{0.75} \times \exp(\theta_5 \times AGE_i)$$

$$\exp(\theta_6) = \Delta^{0.75}$$

$$\theta_6 = 0.75 \log(\Delta)$$

$$\exp\left(\frac{\theta_6}{0.75}\right) = \Delta$$

For the final *UGT2B10* model $\theta_6 = -0.15$, so the equivalent proportional weight reduction is

$$\Delta = \exp\left(\frac{-0.15}{0.75}\right) \approx 0.81$$
