16

17

18 **Abstract**

19 **Introduction.** The aim of this study was to investigate how age and underlying medical conditions
20 affect the risk of severe outcomes following SARS-CoV-2 infection and how they should be
21 weighed while prioritising vaccinations against COVID-19.

22 **Methods.** This population-based register study includes all SARS-CoV-2 PCR-test-positive cases
23 until 24 Feb 2021, based on the Finnish National Infectious Diseases Register. The cases were
24 linked to other registers to identify presence of comorbidities and severe outcomes
25 (hospitalisation, intensive care treatment, death). The odds of severe outcomes were compared in
26 those with and without the pre-specified comorbidities using logistic regression. Furthermore,
27 population-based rates were compared between those with a given comorbidity and those
28 without any of the specified comorbidities using negative binomial regression.

29 **Results.** Age and various comorbidities were found to be predictors of severe COVID-19.
30 Compared to 60–69-year-olds, the odds ratio (OR) of death was 7.1 for 70–79-year-olds, 26.7 for
31 80–89-year-olds, and 55.8 for ≥90-year-olds. Among the 20–69-year-olds, chronic renal disease
32 (OR 9.4), malignant neoplasms (5.8), hematologic malignancy (5.6), chronic pulmonary disease
33 (5.4), and cerebral palsy or other paralytic syndromes (4.6) were strongly associated with COVID-
34 19 mortality; severe disorders of the immune system (8.0), organ or stem cell transplant (7.2),
35 chronic renal disease (6.7), and diseases of myoneural junction and muscle (5.5) were strongly
36 associated with COVID-19 hospitalisation. Type 2 diabetes and asthma, two very common
37 comorbidities, were associated with all three outcomes, with ORs from 2.1 to 4.3. The population-
38 based rate of SARS-CoV-2 infection decreased with age. Taking the 60–69-year-olds as reference,

39 the rate ratio was highest (3.0) for 20–29-year-olds but <1 for 70–79-year-olds and 80–89-year-
40 olds.

41 **Conclusion.** Comorbidities predispose for severe COVID-19 among younger ages. In vaccine
42 prioritisation both the risk of infection and the risk of severe outcomes, if infected, should be
43 combined.

44 **Introduction**

45 Already during summer 2020, the first listings of predisposing conditions for severe COVID-19
46 were published to inform the public on the need to shield the most vulnerable.[1-6] Furthermore,
47 while efficacy studies of COVID-19 vaccines were still being carried out, more detailed research
48 was published on predisposing factors for severe infection outcomes leading to hospitalisation
49 [7,8], intensive care [7,9,10], or death [7,8,11-14]. The implications from these studies have been
50 valuable in planning how to allocate the limited number of vaccine doses optimally to prevent
51 hospitalisations, need to intensive care and deaths.[15] For example, one of the questions was
52 whether the elderly or individuals with certain background illnesses should be prioritised for
53 COVID-19 vaccination.[15] Along with the other European Union countries, Finland joined a
54 common procurement system and subsequently commenced COVID-19 vaccinations in late
55 December 2020.

56 We carried out a country-level analysis of factors predisposing for severe COVID-19 outcomes,
57 based on the possibility to link information across several national health care registers using the
58 unique personal identifier. The specific aim of our study was to investigate how age and presence
59 of underlying medical conditions affect the risk of severe COVID-19 outcomes and how age and
60 medical conditions should be weighed against each other while prioritising vaccination. We thus

61 concentrated on assessing the risk of hospitalisation, intensive care treatment and death in those
62 with SARS-CoV-2 infection, with specific attention to the elderly and persons with certain chronic
63 illnesses and those taking potentially predisposing medications. We here report the results with a
64 particular focus on how these data were used to support effective COVID-19 vaccination
65 intervention in Finland.

66 **Material and Methods**

67 *Data sources and case definitions*

68 The total population of Finland in 2019 was 5.5 million, 51% of which were women. Age- and
69 gender-specific population sizes were obtained from the Finnish Population Information System, a
70 computerised national database which registers individual-based information for all Finnish
71 residents, including name, gender, personal identity code, address, date of birth, and death. The
72 personal identity code remains unchanged throughout the lifetime and is used for patient
73 identification in all health care registers in Finland.

74 We established a dataset comprising virtually the entire Finnish population by linking data from
75 multiple population-based and nationwide registers. This COVID-19 dataset included all individuals
76 with a positive PCR test for SARS-CoV-2 identified between 1 January 2020 and 24 February 2021,
77 based on the Finnish National Infectious Diseases Register. The SARS-CoV-2 cases were linked to
78 other registers in order to identify severe outcomes. Three severe COVID-19 outcomes were
79 defined as inpatient hospitalisation (Care Register for Health Care), admission to intensive care
80 unit (ICU; the Finnish Intensive Care Consortium's Database, FICC), and death within 30 days after
81 the positive PCR test. All cases hospitalised 14 days before or after the positive PCR test with a
82 diagnosis indicating respiratory infection, were considered as COVID-19 outcomes.

83 Individuals with chronic diseases or medical conditions (from now on comorbidities) known as
84 general risk factors of infectious diseases or with risk factors for severe COVID-19 from published
85 studies were identified from the registers using a pre-defined list of diagnoses and codes (Table 1).
86 The following registers were employed: the Care Register for Health Care, the Register of Primary
87 Health Care Visits, as well as the Special Reimbursement Register for Medicine Expenses and
88 Prescription Centre database, both maintained by the Social Insurance Institution of Finland (SII).
89 The dataset covers for the most part all health care providers in Finland. The dataset was linked to
90 the Finnish Population Information System in order to identify individuals without any of the
91 comorbidities potentially predisposing to severe COVID-19 listed in Table 1.

92 Individuals entitled to reimbursement of medicine expenses from 1 January 2020 onwards were
93 identified from the SII register for Special Reimbursements for Medicine Expenses. In Finland, all
94 residents entitled to special reimbursement meet a set of specified medical criteria.

95 Individuals using medication predisposing to immunodeficiency or using medication for type 1 or 2
96 diabetes were identified from the Prescription Centre database maintained by SII. Persons that
97 had any of the prescribed medications of interest not more than two years prior to testing positive
98 for SARS-CoV-2 were identified based on the Anatomical Therapeutic Chemical (ATC) codes.

99 We identified individuals who had used health care services due to any of the specified
100 comorbidities not more than two years (cancer) or five years (all other comorbidities) prior to the
101 positive PCR test. Individuals who had used secondary health care services due the specified
102 comorbidities from the Care Register for Health Care with the International Classification of
103 Diseases 10th revision (ICD-10) codes and the Nordic Classification of Surgical Procedures (NCSP)
104 codes. Individuals who had used primary health care services were identified from the Register of

105 Primary Health Care Visits with ICD-10 codes and the International Classification of Primary Care
106 Second edition (ICPC-2) codes.

107 *Statistical analysis*

108 We estimate the incidence of SARS-CoV-2 infection and severe COVID-19 outcomes by age, sex
109 and comorbidity in individuals with a SARS-CoV-2 infection and in the Finnish population as a
110 whole. The three severe outcomes were hospitalisation, admission to ICU, and death. We first
111 estimated age-specific odds ratios (ORs) for each outcome (e.g. hospitalisation) in SARS-CoV-2
112 cases using logistic regression and adjusting for sex. We next estimated odds ratios, comparing
113 the odds of the outcome (e.g. hospitalisation) in SARS-CoV-2 cases with and without each of the
114 comorbidities, adjusting for age and sex. In addition, negative binomial regression was used to
115 estimate rate ratios (RR) for SARS-CoV-2 infection and the three severe outcomes, comparing
116 individuals with each of the comorbidities with individuals without any of the listed comorbidities
117 (Table 1). The negative binomial model was used instead of Poisson regression to account for
118 overdispersion in the rates. The analysis was adjusted for age and sex.

119 **Results**

120 *Characteristics of the study population*

121 In Finland, a total of 52 502 SARS-CoV-2 cases occurred from 1 March 2020 through 24 February
122 2021, 2743 (5.2%) of which were hospitalised, 538 (1.0%) were admitted to ICU, and 801 (1.5%)
123 died within 30 days after the positive PCR-test (Table 2). The corresponding incidence rates per
124 100 000 person-years were 822.4 for SARS-CoV-2 cases, 43 for hospitalised cases, 8.4 for ICU cases
125 and 12.5 for fatal cases. When restricting to 20–69-year-olds, there were 38 728 SARS-CoV-2

126 cases, 1 916 (4.9%) of which were hospitalised, 403 (1.0%) were admitted to ICU and 98 (0.3%)
127 died within 30 days after the positive PCR-test.

128 The proportion of fatalities among SARS-CoV-2 cases increased with age (Figure 1). In those aged
129 60–69 years, all fatal cases but one had at least one predisposing factor for severe COVID-19. By
130 contrast, in those aged ≥ 70 fatalities occurred also in individuals without any predisposing factors.
131 In 20–69-year-olds, 28% of SARS-CoV-2 cases, 64% of hospitalised cases, 72% of ICU cases, and
132 87% of fatal cases had at least one predisposing factor.

133 The proportion of fatalities among SARS-CoV-2 cases increased with the number of comorbidities
134 (Figure 1). In all age groups, the more comorbidities there were, the higher the mortality was
135 among the infected. With three or more comorbidities the proportion of fatal cases varied from
136 4% (65–69 years) to 32% (75–89 years). In the oldest the proportion of fatal cases was even
137 higher, irrespective of the number of comorbidities.

138 During the study period, SARS-CoV-2 infections were most frequent among 20–29-year-olds,
139 hospitalised cases among 50–59-year-olds, ICU cases among 60–69-year-olds, and fatal cases
140 among 80–89-year-olds (Table 2). The age-specific incidence rates per 100 000 person-years
141 peaked for SARS-CoV-2 infections in those aged 20–29 (1475), for hospitalised cases in those aged
142 80–89 (79.6), for ICU cases in those aged 60–69 (17.6) and for fatal cases in those aged ≥ 90 (289.1)
143 (Figure 2). Severe COVID-19 outcomes were thus clearly over-represented among the elderly. Only
144 6% (3390/52502) of all SARS-CoV-2 cases were detected in individuals aged ≥ 70 (Table 2). Yet 28%
145 (766/2 743) of hospitalised cases, 25% (132/538) of ICU cases and 88% (702/801) of the fatal cases
146 occurred in this age group.

147 *Predictors of hospitalisation, ICU admission and death*

148 According to the logistic regression analysis, the risk of severe COVID-19 outcomes in an individual
149 infected with SARS-CoV-2 increased with age. Compared to 60–69-year-olds, the odds ratio (OR) of
150 death, adjusted for sex, was 7.1 (95% CI 5.3, 9.7) for the 70–79-year-olds, 26.7 (95% CI 20, 36) for
151 the 80–89-year-olds, and 55.8 (95% CI 40.5, 77.9) for the ≥90-year-olds (Table 3a). Furthermore,
152 the OR of hospitalisation was 2.0 (95% 1.8, 2.3) and of ICU admission 1.7 (95% CI 1.3, 2.2) for those
153 aged 70–79 (Table 3a). In addition, male sex was identified as a risk factor for all severe outcomes:
154 hospitalisation (OR 1.3; 95% CI 1.2, 1.4), ICU admission (OR 1.9; 95% CI 1.6, 2.3), and death (OR
155 1.9; 95% CI 1.6, 2.2).

156 The more comorbidities a person had, the higher was their risk of severe COVID-19. The effect was
157 even stronger when the analysis was restricted to 20–69-year-olds (Table 3b). Comparing SARS-
158 CoV-2 cases with three or more comorbidities with cases without any of the comorbidities in
159 question, the age- and sex-adjusted ORs of severe outcomes were 6.6 for hospitalisation (95% CI
160 5.6, 7.7), 9.5 for ICU admission (95% CI 7.0, 12.9), and 16.1 for death (95% CI 8.1, 33.4).

161 Many of the individual comorbidities were clear risk factors for death. Among the 20–69-year-olds
162 the strongest risk factors for death due to COVID-19 were severe chronic renal disease (OR 9.4;
163 95% CI 4.2, 18.8), malignant neoplasms (OR 5.8; 95% CI 3.3, 9.7), hematologic malignancy (OR 5.6;
164 95% CI 1.6, 14.1), chronic pulmonary disease (OR 5.4; 95% CI 2.0, 11.9), and cerebral palsy and
165 other paralytic syndromes (OR 4.6; 95% CI 0.3, 22.6), when comparing the odds between
166 individuals with and without the comorbidity in question (Table 3b). Likewise, cerebrovascular
167 diseases, type 2 diabetes, autoimmune diseases treated with immunosuppressive drugs, use of
168 glucocorticoids, secondary hypertension alone, ischaemic heart diseases and asthma increased the

169 risk of death, with ORs between 2 and 5. Some of the comorbidities were very rare, thus, it was
170 not possible to calculate reliable OR estimates.

171 Strong risk factors for COVID-19 hospitalisation among the 20–69-year-olds were severe disorders
172 of the immune system (OR 8.0; 95% CI 3.5, 17.2), organ or stem cell transplant (OR 7.2; 95% CI 4.0,
173 12.5), chronic renal disease (OR 6.7; 95% CI 4.6, 9.6), diseases of myoneural junction and muscle
174 (OR 5.5; 95% CI 2.9, 10.2) (Table 3b). Likewise, psychotic disorders, chronic pulmonary disease,
175 paralytic syndromes, asthma, hematologic malignancy, type 2 diabetes, cerebrovascular diseases,
176 cardiovascular diseases, autoimmune diseases treated with immunosuppressive drugs, sleep
177 apnea, and the use of clozapine, immunosuppressants or biologic drugs increased the risk of
178 hospitalisation, with ORs between 2 and 5. The severity of the comorbidity was associated with
179 severe disease outcomes. The risk of hospitalisation and admission to ICU was higher for asthma
180 and type 2 diabetes cases that had been treated in secondary health care (Figure 3).

181 According to the negative binomial regression model, the population-based rate of SARS-CoV-2
182 infection decreased with age. Compared to the 60–69-year-olds, the rate was 3.0-times higher in
183 20–29-year-olds (RR 3.0; 95% CI 2.8, 3.3) and 2.4-times higher in 30–39-year-olds (RR 2.4; 95% CI
184 2.2, 2.5), but somewhat lower in 70–79-year-olds (RR 0.7; 95% CI 0.6, 0.7) and 80–89-year-olds (RR
185 0.9; 95% CI 0.9, 1). The higher rate of SARS-CoV-2 infection in the ≥90-year-olds (RR 1.5; 95% CI
186 1.4, 1.7) can be explained by local epidemics which occurred in nursing homes. However, the rate
187 of SARS-CoV-2 infection did not differ between females and males. Compared to the 60–69-year-
188 olds, the population-based rate of hospitalisation was higher among the 50–59-year-olds (RR 1.3;
189 95% CI 1.2, 1.4) and the risk of ICU admission was higher among the 50–59-year-olds (RR 1.2; 95%
190 CI 1.0, 1.4).

191 In addition, for each comorbidity, we report the relative rates of hospitalisation, ICU admission
192 and death in the 20–69-year-olds, comparing individuals with the comorbidity with those without
193 any of the specified comorbidities (Table 4). The rate of SARS-CoV-2 infection was roughly the
194 same for most of the comorbidities when comparing to those without any of the specified
195 comorbidities (Table 4). However, some differences were obvious, e.g. those using clozapine (RR
196 0.5; 95% CI 0.4, 0.7), with psychotic disorders (RR 0.6; 95% CI 0.5, 0.7) and heart failure, (RR 0.7;
197 95% CI 0.6, 0.9) had lower rates of SARS-CoV-2 infection. By contrast, the relative rate of severe
198 COVID-19 outcomes in the 20–69-year-olds, when comparing to those without any of the specified
199 comorbidities varied, e.g. For hospitalisation it was 5.1–8.9-times higher for organ or stem cell
200 transplant, severe chronic renal disease, severe disorders of the immune system, diseases of
201 myoneural junction and muscle and type 2 diabetes.

202 At the upper part of Table 4, 60–69-year-olds is the reference category, and the rate ratios
203 presented for each comorbidity and outcome at the bottom part of the table can be taken to
204 present relative rates in that age group. The additional risk caused by a specific comorbidity at any
205 other age category can be obtained by multiplying the rate ratio of interest at a lower part of the
206 table by the rate ratio of the age group of interest. For almost all comorbidities, the relative risks
207 of dying for 50–59-year-olds with comorbidities, were greater than for 60–69-year-olds without
208 any comorbidities. For example, the risk for 55-year-old person with chronic pulmonary disease to
209 die of COVID-19 is almost 10 times (0.5×19.5) of that of 65-year-old person without any of the
210 listed conditions.

211 **Discussion**

212 In this population-based setting we estimated the risks for four entities: SARS-CoV-2 infection and
213 COVID-19 related hospitalisation, ICU admission and death by age and various comorbidities or
214 conditions. Age and certain comorbidities were found to be predictors of severe COVID-19 in cases
215 of SARS-CoV2 infection. Old age was strongly associated with mortality, and having multiple
216 comorbidities was associated with both mortality and hospitalisation. The estimation of
217 population-based rates of hospitalisation and death related to SARS-CoV-2 infection allowed an
218 even more detailed characterisation of the relative roles of age and comorbidities as risk factors
219 for severe COVID-19. Based on this analysis, vaccination of the elderly aged ≥ 70 years was
220 prioritised in Finland, followed by vaccination of those with highly predisposing medical
221 conditions.[16]

222 As expected, immunosuppressive states such as organ or stem cell transplantation, severe
223 disorders of the immune system or severe renal disease were associated with increased risks of
224 hospitalisation and ICU admission due to COVID-19. Similar results were obtained in a population-
225 based Danish study where organ transplantation and severe kidney disease were the two medical
226 conditions associated with the highest risks of severe COVID-19.[7] In an English study, which
227 recorded nearly 11 000 deaths in a cohort of more than 17 million SARS-CoV-2 positive patients,
228 organ transplantation was associated with the highest risk of death due to COVID-19 (hazard ratio
229 6.0; 95% CI 4.7, 7.6) among the studied medical conditions, after the analysis was adjusted for age
230 and sex.[11] Furthermore, in our study patients with an autoimmune disease, those receiving
231 immunosuppressive drug therapy were more prone to severe outcomes than patients without
232 such therapy. Potential reasons for the increased risk are the immunosuppressive medication itself

233 and the increased severity of the underlying disease that necessitated an immunosuppressive drug
234 therapy.

235 Among SARS-CoV-2 cases aged 20-69, the relative risk of death was higher in patients with chronic
236 renal or liver disease, diseases of myoneural junction and muscle, cerebral palsy or other paralytic
237 syndromes as well as in those with psychotic disorders, especially with prescription for the
238 psychiatric medication clozapine. The association of psychiatric disorders and high COVID-19
239 mortality has been explained only partly by the presence of other comorbidities. [17] Other
240 reasons such as socioeconomic factors, delays in treatment seeking and certain deficits in cellular
241 immunity in schizophrenia have been implicated.[17] Although it is known that clozapine causes
242 neutropenia and predisposes for pneumonia[18] its role in COVID-19 infections has not been asessed
243 broadly.

244 In our analysis, asthma, similarly to other chronic pulmonary diseases, was associated with higher
245 risk of hospitalisation and intensive care treatment, but it was not associated with higher
246 mortality. The association with hospitalisation was weaker but present even when asthma had
247 been treated in primary health care only, indicating a presumably less severe manifestation.

248 However, in a review and meta-analysis where 76 studies and more than 17 million SARS-CoV-2
249 positive patients were included, asthma was not associated with severe COVID-19.[19] In our
250 study, 4.7% of 20–69-year-old SARS-CoV-2 cases were recognized as having asthma although the
251 overall prevalence in Finland is twice as high.[16] Our estimate is likely to represent the risk for
252 more severe asthma. In line with that, recent treatment of asthma with corticosteroids, indicating
253 a more severe manifestation, has been reported to be associated with an increased risk of severe
254 COVID-19 in some studies.[7,11]

255 Although they are no typical predictors for other infectious diseases, it has been widely noted that
256 metabolic syndrome and obesity as well as type 2 diabetes are strongly associated with higher
257 risks of severe COVID-19.[11,12,14,20] In our study, type 2 diabetes, which often occurs together
258 with obesity and metabolic syndrome, was associated with higher risks of severe COVID-19 and
259 death than the more serious disease, type 1 diabetes. In addition to obesity, regulation of blood
260 glucose levels might play a role in the progression of SARS-CoV-2 infections among type 2 diabetes
261 patients as high blood sugar levels have been shown to predict severe COVID-19.[11,20,21]
262 Moreover, type 2 diabetes has been identified as an prognostic factor for survival among COVID-
263 19 cases requiring critical care especially among the middle-aged and younger.[14]

264 In many studies, hypertension has been more prevalent among severe or fatal COVID-19 cases
265 than among milder cases.[22] Also in our study, hypertension was more prevalent among severe
266 cases; while only 7% of the SARS-CoV-2 positive 20-69-year-old individuals were hypertensive,
267 25%, 32% and 36% of the hospitalised, ICU and fatal 20-69-year-old cases suffered from
268 hypertension. However, patients who had only hypertension were not at increased risk of severe
269 outcomes according to our study; similar results have been obtained elsewhere.[23] Since
270 hypertension is common in patients who also have other comorbidities predisposing for severe
271 COVID-19, such as obesity, hypertension alone is not an appropriate indicator for the prioritisation
272 of COVID-19 vaccination.

273 The main strength of our study is the utilisation of multiple national registers, across which
274 individual-level data were linked via a unique personal identifier. Information on possible
275 predisposing comorbidities could therefore be verified from different sources. Furthermore, not
276 only the conditional risk of hospitalisation given SARS-CoV-2 infection but also the rate of SARS-

277 CoV2 infection could be evaluated based on our nationwide dataset. It is a strength of our study
278 that the effect of comorbidities on the risk on severe COVID-19 was analysed among the 20-69-
279 year-olds, excluding the elderly, which should be prioritised by their age in any case.

280 Our study is solely based on register data. Therefore, we could not address the severity of the
281 underlying comorbidities to any further extent than what could be deduced from the recorded
282 diagnoses and medications. Another weakness is the rather limited number of cases, although we
283 included all laboratory-confirmed SARS-CoV-2 cases that had occurred by 24 February 2021.

284 During the study period, non-pharmaceutical interventions reduced the spread of COVID-19 in
285 Finland considerably. Additionally, not all national registers are adequate for real-time use. For
286 example, the Finnish Cancer Register is updated only annually, so that, at the time of the study,
287 data from 2019 and beyond were not yet available. Therefore, we could not utilise more detailed
288 data from the Cancer register on the status or treatment of cancers and, therefore, could not
289 identify cases receiving immunosuppressive treatments. Furthermore, the national registers used
290 to identify individuals with the specified comorbidities did not contain private or occupational
291 health care visits. However, if any disease entitling a special reimbursement is diagnosed at those
292 visits, it is registered in the SII and thus included in our dataset.

293 When vaccinations are targeted to prevent severe COVID-19 among those with very common
294 comorbidities, the number of vaccine doses needed is reasonably high. However, if we assume
295 that vaccination prevents all severe cases (e. g. hospitalisations) and that the whole population,
296 without vaccinations, would eventually acquire SARS-CoV-2 infection, the number needed to
297 vaccinate to prevent one COVID-19 hospitalisation would remain small even for common diseases:

298 only 4.8 (1293 infections / 271 hospitalisations; Table 2) for type 2 diabetes, 6.1 for sleep apnea
299 and 7.3 for asthma.

300 According to our study, vaccination of the more critically ill, for example, patients with heart
301 failure or type 1 diabetes, is in fact slightly less effective in preventing severe COVID-19: the risks
302 of hospitalisation, intensive care treatment and death, conditional on SARS-CoV-2 infection, are
303 lower than among type 2 diabetes patients. Furthermore, in Finland patients with heart failure
304 and type 1 diabetes were less likely to have a SARS-CoV-2 infection than patients with type 2
305 diabetes or asthma. These findings may follow from effective shielding of the most vulnerable,
306 i.e., strict adherence to the nonpharmaceutical interventions recommended. If in the future we
307 are in a similar situation again (new pathogen, vaccine scarcity), this kind of study is the key.

308 **Authors' contributions**

309 HS, TL (Tuija), TL (Toni) conceptualized the study. TL (Toni) and UB conducted the statistical
310 analysis. TL (Tuija) reviewed the literature. HS, TL (Tuija) and KA drafted the manuscript. All
311 authors discussed the results and contributed to the final manuscript.

379 Table 1. Comorbidities identified as potential risk factors predisposing to severe COVID-19

Comorbidities	Classification system	Codes	Register
Organ or stem cell transplant	ICD-10	T86, Z94	1,2
Malignant neoplasms	ICD-10	C00–C43, C45–C80, C97, D05.1, D39	1,2
Hematologic malignancy	ICD-10	C81–C85, C88, C90–C96	1,2
Severe disorders of the immune system	ICD-10	D70.8, D80–D84, E31.00	2
Severe chronic renal disease	ICD-10	I12, I13, N00–N05, N07, N08, N11, N14, N18, N19, E10.2, E11.2, E14.2	1,2
Severe chronic liver disease	ICD-10	K70.2, K70.3, K70.4, K71–K74	2
Asthma	ICD-10	J45, J46	2, 3
	ICPC-2	R96	3
Chronic pulmonary disease	ICD-10	J41–J44, J47	2
Essential (Primary) Hypertension	ICD-10	I10	1, 3
	ICPC-2	K86	3
Hypertensive heart and/or renal disease, secondary hypertension	ICD-10	I11.9, I12, I13.1, I13.9, I15	1,2
Ischaemic heart diseases	ICD-10	I20–I25	1,2
Heart failure	ICD-10	I11.0, I13.0, I13.2, I50	1,2
Type 1 diabetes	ICD-10	E10	2, 3
	ICPC-2	T89	3
	ATC	A10A	4
Type 2 diabetes	ICD-10	E11, E13, E14	2,3
	ICPC-2	T90	3
	ATC	A10B	4
Diseases of myoneural junction and muscle	ICD10	G70–G73	2
Cerebral palsy and other paralytic syndromes	ICD10	G80–G83	2
Cerebrovascular diseases	ICD-10	I60–I69	2
Sleep apnea	ICD-10	G47.3	2, 3
Continuous positive airway pressure therapy	NCSP	WX723, WX780	2
Clozapine (prescription for)	ATC	N05AH02	4
Psychotic disorders	ICD-10	F20–F29	2, 3
	ICPC-2	P72	3
Autoimmune disease	ICD-10	D86, K50, K51, L40, M02, M05–M07, M13.9, M45, M46.0, M46.1, M46.9, M94.1	1, 2
Glucocorticoids (prescription for)	ATC	H02AB02, H02AB04, H02AB06, H02AB07	4
Biologic drugs (entitlement to reimbursement of medical expenses)	ATC	L04AA24, L04AB01, L04AB02, L04AB04, L04AB05, L04AB06, L04AC03, L04AC05, L04AC07, L04AC10, L04AC12, L04AC13, L04AC14, L04AC16, L04AC18	1
Biologic drugs, Tumor necrosis factor alpha (TNF- α) inhibitors (Prescription for)	ATC	L04AB	4
Biologic drugs, other (prescription for)	ATC	L01XC02, L04AA24, L04AA26, L04AA33, L04AC	4
Other Immunosuppressant drugs	ATC	L01BA01, L04AA06, L04AA10, L04AA13, L04AA18, L04AA29, L04AA37, L04AD01, L04AD02, L04AX01, L04AX03	4

380 ATC, Anatomical Therapeutic Chemical Classification System; ICD-10, International Statistical Classification
381 of Diseases and Related Health Problems, tenth revision; ICPC-2, International Classification of Primary
382 Care, second edition; NCSP, Nordic Nomesco Classification of Surgical Procedures.

400
401
402

¹ Compared to the individuals without any of the comorbidities in question.
² Comparing the odds of each outcome with and without the comorbidities in question.

403

404

405 Table 4. Relative rates of SARS-Cov-2 infection and severe COVID-19 outcomes (hospitalisation, admission to ICU and death) in the Finnish population aged
 406 20–29, based on a negative binomial regression model. The table presents rate ratios (RR) and 95% confidence intervals (CI 95%).

	RR (95% CI)	Hospitalised	Hospitalised, ICU	Fatal cases
	SARS-CoV-2 PCR-positive			
Age, years				
20–29	3.1 (2.9, 3.3)	0.4 (0.3, 0.5)	0.2 (0.1, 0.3)	0.1 (0, 0.3)
30–39	2.4 (2.3, 2.5)	0.8 (0.7, 0.9)	0.5 (0.4, 0.7)	0.2 (0.1, 0.3)
40–49	2.3 (2.2, 2.4)	1.2 (1, 1.3)	0.9 (0.8, 1.2)	0.3 (0.2, 0.4)
50–59	1.8 (1.8, 1.9)	1.3 (1.2, 1.5)	1.2 (1, 1.4)	0.5 (0.4, 0.7)
60–69	1.0 (ref)	1.0 (ref)	1.0 (ref)	1.0 (ref)
Sex				
Male	1 (1, 1)	1.3 (1.2, 1.4)	1.2 (1.1, 1.3)	2.1 (1.8, 2.3)
Female	1.0 (ref)	1.0 (ref)	1.0 (ref)	1.0 (ref)
Comorbidities, 20–69-year-olds¹				
Organ or stem cell transplant	1 (0.8, 1.3)	8.9 (5.5, 13.8)	20.7 (9.7, 38.6)	15.2 (0.8, 76.6)
Malignant neoplasms	1 (0.9, 1.1)	3.1 (2.3, 4)	3.6 (2.1, 5.7)	20.7 (10, 43.9)
Hematologic malignancy	1 (0.8, 1.2)	4.7 (2.9, 7.2)	7.6 (3.2, 15.3)	25.9 (7.2, 73.9)
Severe disorders of the immune system	0.9 (0.6, 1.2)	7.5 (3.7, 13.5)	4.7 (0.3, 20.8)	NA
Severe chronic renal disease	1 (0.8, 1.1)	8.3 (6, 11.3)	14.3 (8.2, 23.2)	46.4 (19, 108.7)
Severe chronic liver disease	0.9 (0.7, 1.1)	2.7 (1.3, 4.9)	4.8 (1.2, 12.7)	38.6 (10.8, 110.3)
Asthma	1.1 (1.1, 1.2)	4.8 (4, 5.9)	9.5 (7.1, 12.7)	9.8 (4.3, 22.1)
Chronic pulmonary disease	0.8 (0.7, 1)	4.6 (3.1, 6.6)	7.4 (3.9, 13)	19.5 (6.8, 50.1)
Primary or secondary hypertension	0.9 (0.9, 1)	3.5 (2.8, 4.2)	4.9 (3.8, 6.4)	7.5 (4, 15)
Essential (primary) hypertension alone	1 (0.9, 1.1)	1.8 (1.3, 2.4)	1.6 (0.8, 3)	2.2 (0.4, 8.2)
Secondary hypertension (hypertensive heart and/or renal disease) alone	0.8 (0.7, 0.9)	2.9 (2.3, 3.7)	5.6 (4, 7.7)	9.1 (4.4, 19.1)
