

## SUPPLEMENTAL INFORMATION

**Supplemental Table 1. Kinship coefficient of Amish subpopulations by primary recruitment site and cognitive impairment status.**

Group	Mean Kinship Coefficient
All Amish adults	0.003703
Primary site: Ohio	0.006157
Primary site: Indiana	0.005290
Cognitively Normal	0.003909
Cognitively Impaired	0.003793

**Supplemental Figure 1. Age distribution of Amish and non-Amish populations.** We observe that the age distributions of the populations are not identical and include many younger individuals, especially in the non-Amish comparison group. This justifies the use of an analysis after age subset in the case of an age-related disease, such as Alzheimer disease.

**Supplemental Figure 2. PRS distributions in Amish with cognitive impairment as primary outcome.** We observe that the Jansen et al. (2019)<sup>17</sup> polygenic risk score is capable of distinguishing between Amish affected by cognitive impairment and unaffected by cognitive impairment ( $p=0.002$ ). *Abbreviations: CI = cognitively impaired.*
