

Vaccination is the most important COVID-19 public health action even though herd immunity is unlikely: Technical appendix

1. Calibrating transmission and the next-generation matrix

To model the transmission of SARS-CoV-2 we stratify the population into 16 5-year age bands $i \in \{0 - 4, 5 - 9, 10 - 14, \dots, 70 - 74, 75+\}$ and assume that individuals in age group i possess a relative susceptibility to infection u_i . Once infected, an age-dependent fraction y_i go on to develop symptomatic (i.e., clinical) disease whilst the remaining $1 - y_i$ develop asymptomatic (i.e., sub-clinical) disease. We assume that individuals in the sub-clinical class are less infectious than those in the clinical class by a relative factor f (baseline value 0.25 (Davies et al. 2020)) and that the total time spent infectious for both classes is τ days (Davies et al. 2020).

Each day, each individual in age group j makes c_{ij} contacts with individuals in age group i leading to the following expression for the (unscaled) next-generation matrix (NGM) (Davies et al. 2020, Diekmann et al. 2010):

$$\bar{K}^u_{ij} = \frac{u_i S_i c_{ij}}{N_j} [y_j + (1 - y_j)f]\tau$$

where S_i is the number of susceptible individuals in age group i and N_j is total number of individuals in age group j . We allow that prior to vaccination an age-specific fraction p_i of individuals have immunity as a result of previous infection, such that $S_i = (1 - p_i)N_i$.

The (i, j) th entry of the 16×16 NGM \bar{K}^u is proportional to the average number of new infections in age group i generated by an individual in age group j over their entire infectious lifetime. To calculate the actual number of infections generated by each individual these entries must be scaled by the (pseudo-)probability of transmission given contact, which we denote by η . In particular, the basic reproduction number, R_0 , which is proportional to the maximal eigenvalue of \bar{K}^u , can be expressed as

$$R_0 = \eta \rho(\bar{K}^u) \quad \Rightarrow \quad \eta = \frac{R_0}{\rho(\bar{K}^u)}$$

where we use $\rho(\bar{K}^u)$ to denote the spectral radius of the matrix $\rho(\bar{K}^u)$.

Incorporating this definition of η along with the possibility of pre-existing immunity p_i the next-generation matrix K^u is given by

$$K^u_{ij} = \eta \cdot \frac{u_i S_i c_{ij}}{N_j} [y_j + (1 - y_j)f]\tau.$$

For a given R_0 we use the expression given above to calculate the scaling factor η in terms of R_0 and $\rho(\bar{K}^u)$. Daily, age-specific contact rates c_{ij} are provided by the synthetic matrices presented in (Prem et al. 2020).

2. Incorporating vaccination

In the presence of vaccination we further subdivide the population into those who are vaccinated and those who are unvaccinated. Individuals who are vaccinated experience a reduced risk of

acquiring infection (by a factor $1 - V^{\text{acq}}$), a reduced risk of symptomatic disease (by a factor $1 - V^{\text{sev}}$), and are potentially less infectious (by a factor $1 - V^{\text{trans}}$). Each of these factors is dependent on the combination of SARS-CoV-2 strain and vaccine. If a proportion v_i of individuals in age group i are vaccinated, then the modified 16×16 next-generation matrix in the presence of vaccination is given by

$$K^{\text{vac}}_{ij} = \eta \cdot \frac{u_i S_i c_{ij}}{N_j} \{ [y_j + (1 - y_j)f](1 - v_j) + [(1 - V^{\text{sev}})y_j + (1 - (1 - V^{\text{sev}})y_j)f](1 - V^{\text{trans}})(1 - V^{\text{acq}})v_j \} \tau.$$

Note that this expression only stratifies the population according to age (i.e., the indices i, j only run over the 16 age groups we have specified above). If we wish to additionally track the transmission rates between individuals of different ages and different vaccination status, then we can use the expanded (32×32) next-generation matrix \tilde{K} , which can be expressed as the matrix product:

$$\tilde{K} = \begin{bmatrix} 1 - v \\ (1 - V^{\text{acq}})v \end{bmatrix} [K^u \quad K^v]$$

where the terms $1 - v$ and $(1 - V^{\text{acq}})v$ in the first factor are 16×16 diagonal matrices, the matrix K^u is defined above and

$$K^v_{ij} = \eta \cdot \frac{u_i S_i c_{ij}}{N_j} [(1 - V^{\text{sev}}v_j)y_j + (1 - (1 - V^{\text{sev}}v_j)y_j)f](1 - V^{\text{trans}}v_j)\tau.$$

3. Calculating the final size and disease-related mortality

To calculate the total number of infections and deaths throughout the course of the epidemic we use the vectorized form of the final size equation given by (Andreasen 2011):

$$1 - \tilde{z}_i = \exp \left[-\tilde{N}_i^{-1} \sum_j \tilde{K}_{ij} \tilde{N}_j \tilde{z}_j \right]$$

where \tilde{z}_i is the fraction of individuals in group i that become infected throughout the epidemic, \tilde{N}_i is the population size of group i and \tilde{K}_{ij} is the extended next-generation matrix defined in the previous section. Note that here we use the extended (32×32) next-generation matrix \tilde{K}_{ij} that stratifies by both age and vaccination status because the infection-fatality rate for vaccinated individuals is reduced by a factor $1 - V^{\text{sev}}$ relative to those that are unvaccinated. Moreover, the population size $\tilde{N} = ((1 - v_i)N_i, v_i N_i)$ is a combined vector of the number of vaccinated and unvaccinated individuals in each age group.

Solving the final size equation numerically, we can determine the total number of deaths D using the following expression:

$$D = \sum_{i \in \{0-4, \dots, 75+\}} d_i [(1 - v_i) + (1 - V^{\text{sev}})v_i](1 - p_i)S_i$$

where d_i is the age-specific infection-fatality rate (O'Driscoll et al. 2020). These values are listed in Table 2.

4. Parameter values

Table 1. Model parameters.

Parameter	Description	Value
u_i	Relative susceptibility of age group i	See Table 2
y_i	Fraction of infected individuals in age group i that develop clinical symptoms	See Table 2
τ	Infectious period	5.0 days
f	Relative infectiousness of asymptomatic individuals	0.25
p_i	Fraction of individuals in age group i with pre-existing immunity	0.016
η	(Pseudo-)Probability of transmission given contact	Fitted
v_i	Proportion of vaccinated individuals in age group i	Variable

Table 2. Age-specific epidemiological parameters. Data for age-specific relative susceptibility and clinical fraction taken from (Davies et al. 2020); data for infection-fatality rate taken from (O’Driscoll et al. 2020).

Age group (years)	Relative susceptibility (u_i)	Clinical fraction (y_i)	Infection-fatality rate (d_i)
0-4	0.39	0.28	2.98E-05
5-9	0.39	0.28	6.9E-06
10-14	0.38	0.2	1.1E-05
15-19	0.38	0.2	2.57E-05
20-24	0.79	0.26	7.88E-05
25-29	0.79	0.26	0.000171
30-34	0.87	0.33	0.00033
35-39	0.87	0.33	0.000545
40-44	0.80	0.4	0.001052
45-49	0.80	0.4	0.001675
50-54	0.82	0.49	0.002992
55-59	0.82	0.49	0.004583
60-64	0.89	0.63	0.006017
65-69	0.89	0.63	0.015209
70-74	0.74	0.69	0.024209
75+	0.74	0.69	0.043257

Table 3. Vaccine efficacy.

Vaccine	Clinical trial efficacy (95% CI)	Efficacy against acquisition (V^{acq})	Efficacy against severe disease (V^{sev})	Efficacy against transmission (V^{trans})
BNT162b2 (Pfizer)	0.879 (0.782, 0.932)	0.758	0.5	0.5

ChAdOx1 (AstraZeneca)	0.598 (0.289, 0.773)	0.362	0.37	0.5
