Supplementary Note 1: Associations between 737 lead SNPs with lipid species and metabolites in previous studies. We identified 35 previous studies that had reported one or more of our 737 lead SNPs or a proxy ($R^2 > 0.8$) (Supplementary Table 13); details below.

Supplementary Note 2: Regional association plots for lipid loci that colocalize with coronary artery disease. We identified 47 putative shared causal variants from colocalization analysis of lipid loci (Supplementary Table 16). Shown is the regional association plot of coronary artery disease³⁶ and up to the top four lipid species that show evidence of colocalization ($H3+H4 > 0.8$; $H4/H3 > 10$). Regions were isolated from the 737 lead SNPs, with a window of 400 KB centred on the lead SNP. The indicated candidate SNP was the genetic variant with the largest posterior probability. Marker colours indicate linkage disequilibrium with the candidate SNP (obtained from the 1000 Genome European dataset). Colocalization sensitivity analysis was performed for the top colocalization, assessing the posterior probability of H0-H4 for different values of prior p_{12} . Shaded regions indicate the value of p_{12} which produces posterior probabilities of $H3+H4 > 0.8$ and $H4/H3 > 10$.

Supplementary Note 3: Comparison of estimated lipidomic effect sizes. To assess the impact of adjusted for clinical lipid traits or to assess the difference between adjusted and mtCOJO GWAS results, we calculated t-statistics for the difference in beta-coefficients.

$$t = \frac{\beta_{STD} - \beta_{ADJ}}{\sqrt{SE(\beta_{STD})^2 + SE(\beta_{ADJ})^2}}$$

Where β_{ADJ} and β_{STD} are the estimated genetic effects from models with and without adjustment for clinical lipid traits, respectively. $SE(\beta)$ is the estimated standard error of the estimates.
