34 Overview of analysis

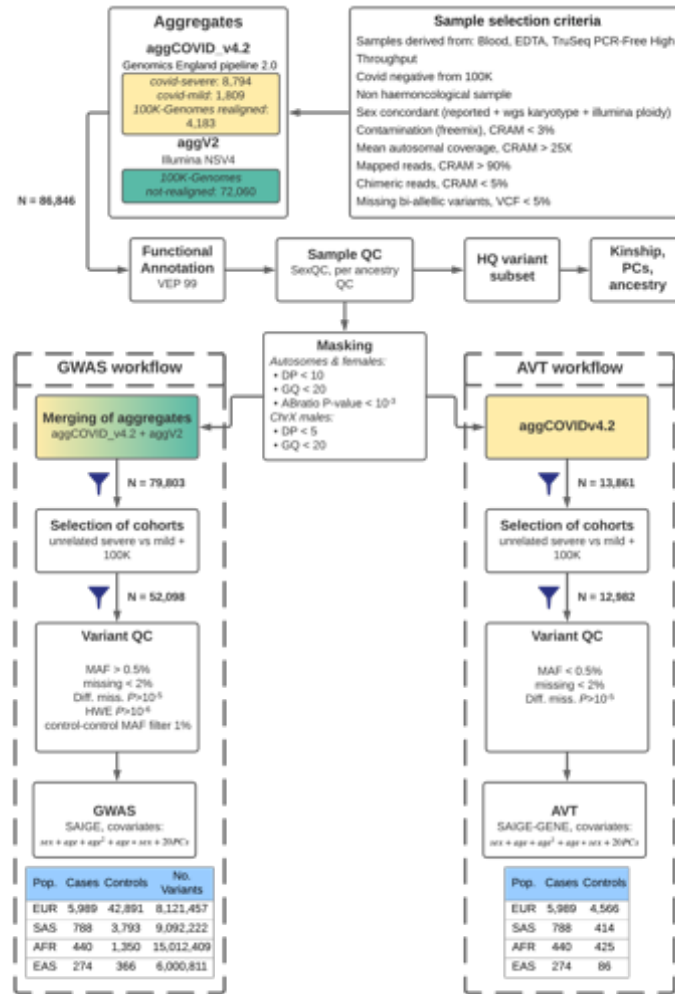

Figure 1: Diagram showing the analysis workflow for genome-wide association study (GWAS) and aggregate variant testing (AVT) analyses of this study.

35 **Cohort characteristics**

36 **Pre-QC breakdown**

Cohort	Instrument	Alignment & variant calling workflow	N (pre-QC)	Included in aggregate
<i>covid - severe</i>	NovaSeq	Genomics England pipeline 2.0	8,794	aggCOVID_v4.2
<i>covid - mild</i>	NovaSeq	Genomics England pipeline 2.0	1,809	aggCOVID_v4.2
<i>100K-Genomes(not realigned)</i>	Hiseq X	Illumina North Star Version 4 (NSV4, version 2.6.53.23)	72,060	aggV2
<i>100K-Genomes(realigned)</i>	Hiseq X	Genomics England pipeline 2.0	4,183	aggCOVID_v4.2

Table 1: Breakdown of the cohorts included in this study

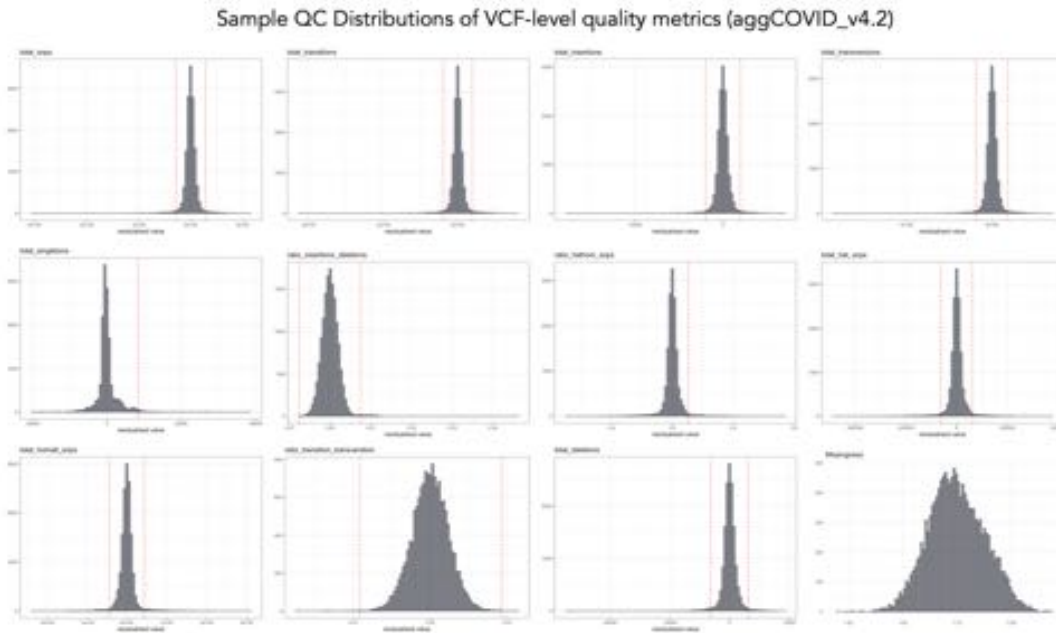

Figure 2: Each histogram shows the distribution of samples in the aggCOVID v4.2 data-set for a particular VCF-level quality metric, following adjustment for sequencing platform and the first three ancestry assignment principal components (as described in Methods). All metrics are calculated from autosomal bi-allelic SNVs. The dashed red lines indicate the threshold for sample exclusion. Samples were removed that were four median absolute deviations (MADs) above or below the median for the following metrics: ratio heterozygous-homozygous, ratio insertions-deletions, ratio transitions-transversions, total deletions, total insertions, total heterozygous snps, total homozygous snps, total transitions, total transversions. For the number of total singletons (snps), samples were removed that were more than 8 MADs above the median. For the ratio of heterozygous to homozygous alternate snps, samples were removed that were more than 4 MADs above the median. For sample-missingness (bottom-right panel), a hard cut-off of 0.05 was applied (no adjustment for sequencing platform or ancestry).

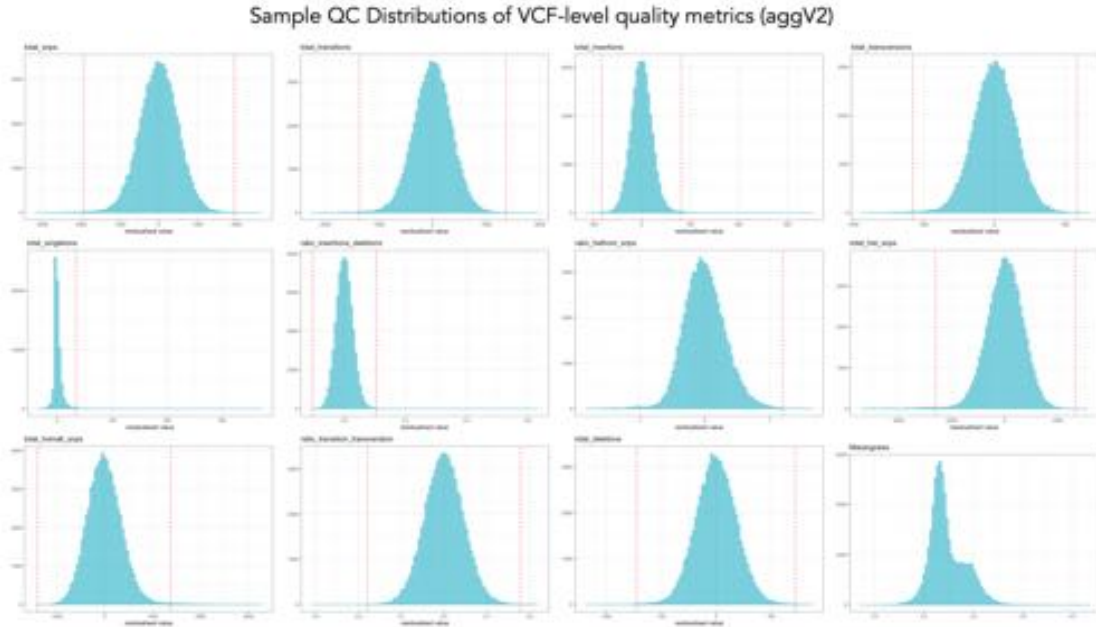

Figure 3: Each histogram shows the distribution of samples in the aggV2 data-set for a particular VCF-level quality metric, following adjustment for sequencing platform and the first three ancestry assignment principal components (as described in Methods). All metrics are calculated from autosomal bi-allelic SNVs. The dashed red lines indicate the threshold for sample exclusion. Samples were removed that were four median absolute deviations (MADs) above or below the median for the following metrics: ratio heterozygous-homozygous, ratio insertions-deletions, ratio transitions-transversions, total deletions, total insertions, total heterozygous snps, total homozygous snps, total transitions, total transversions. For the number of total singletons (snps), samples were removed that were more than 8 MADs above the median. For the ratio of heterozygous to homozygous alternate snps, samples were removed that were more than 4 MADs above the median. For sample-missingness (bottom-right panel), a hard cut-off of 0.05 was applied (no adjustment for sequencing platform or ancestry).

38 **PCA and ancestry**

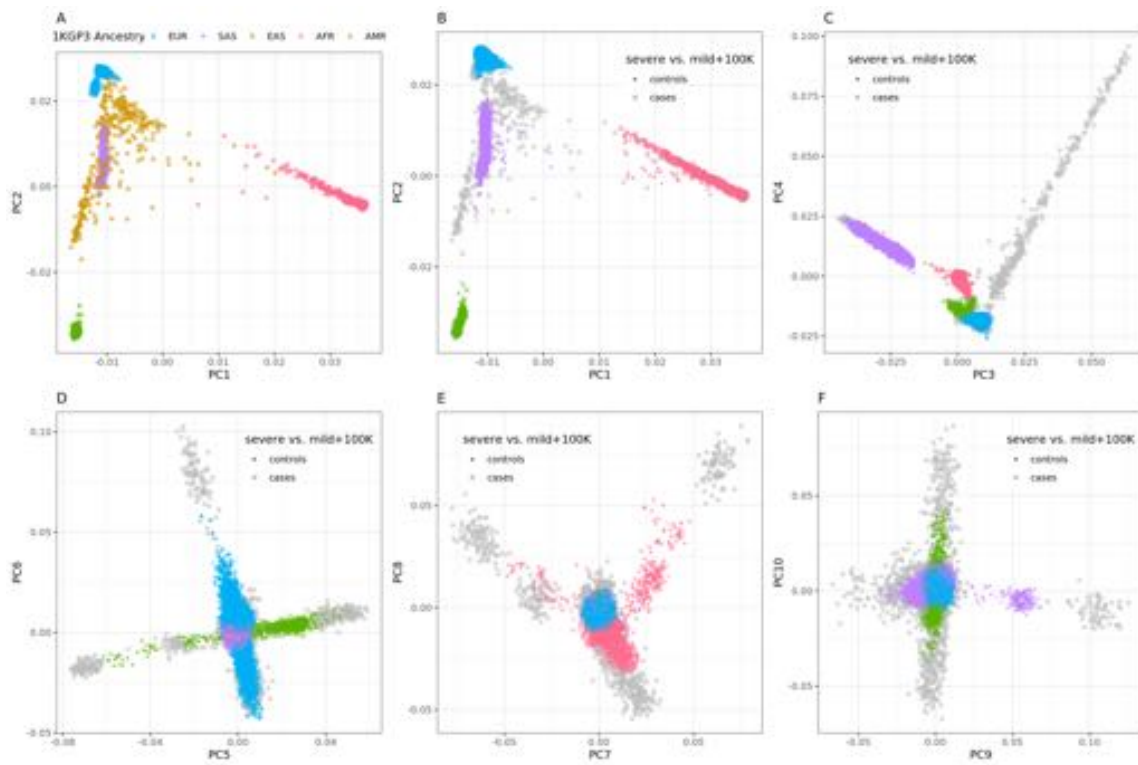

Figure 4: Projection of severe, mild and 100K individuals onto the PCs of the 1KGP3. (A) PCs 1 & 2 for 1KGP3 unrelated individuals using the high quality independent SNP set. (B-F). Projected PCs 1-10 for severe (cases) and mild + 100K individuals (controls). 1KGP3 reference individuals are shown in grey.

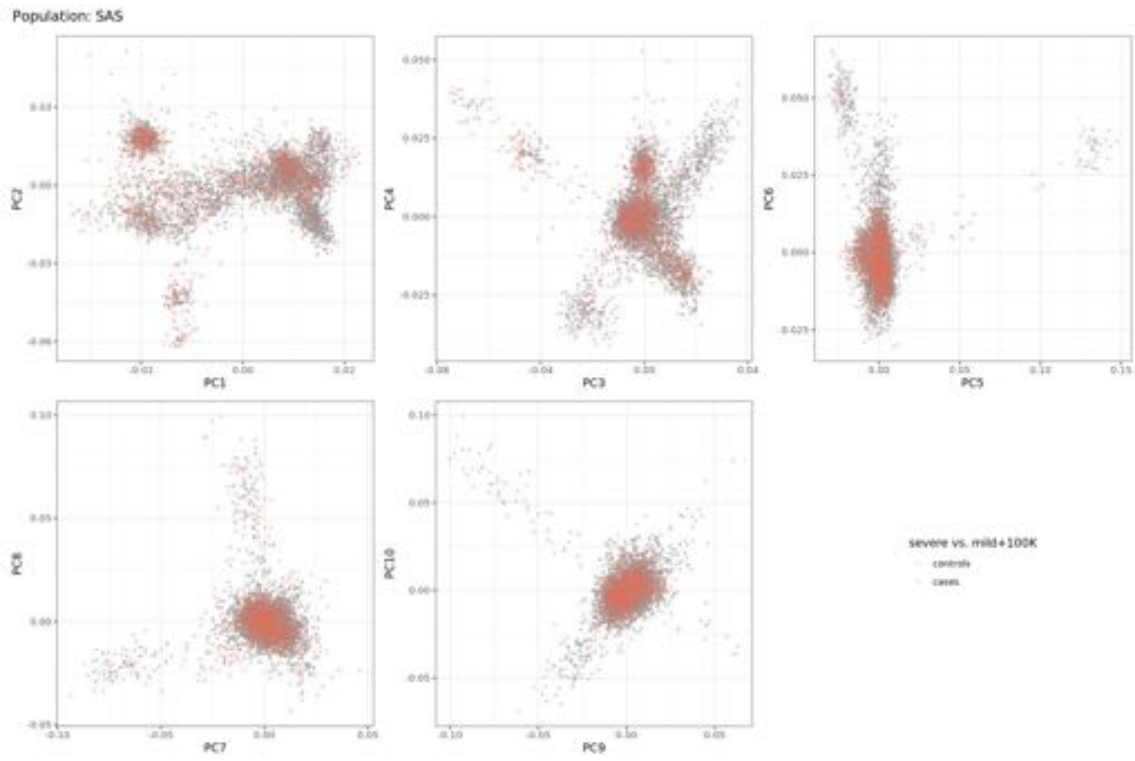

Figure 6: SAS PCs 1-10 for severe (cases) and mild + 100K individuals (controls).

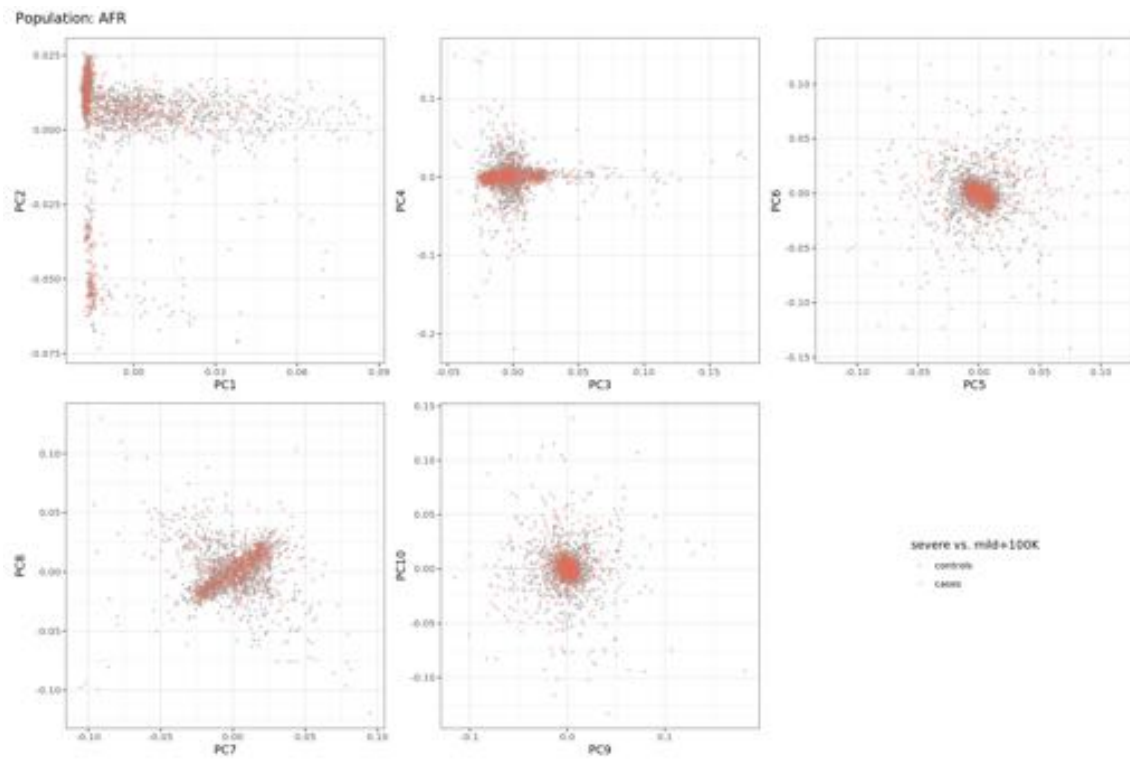

Figure 7: AFR PCs 1-10 for severe (cases) and mild + 100K individuals (controls).

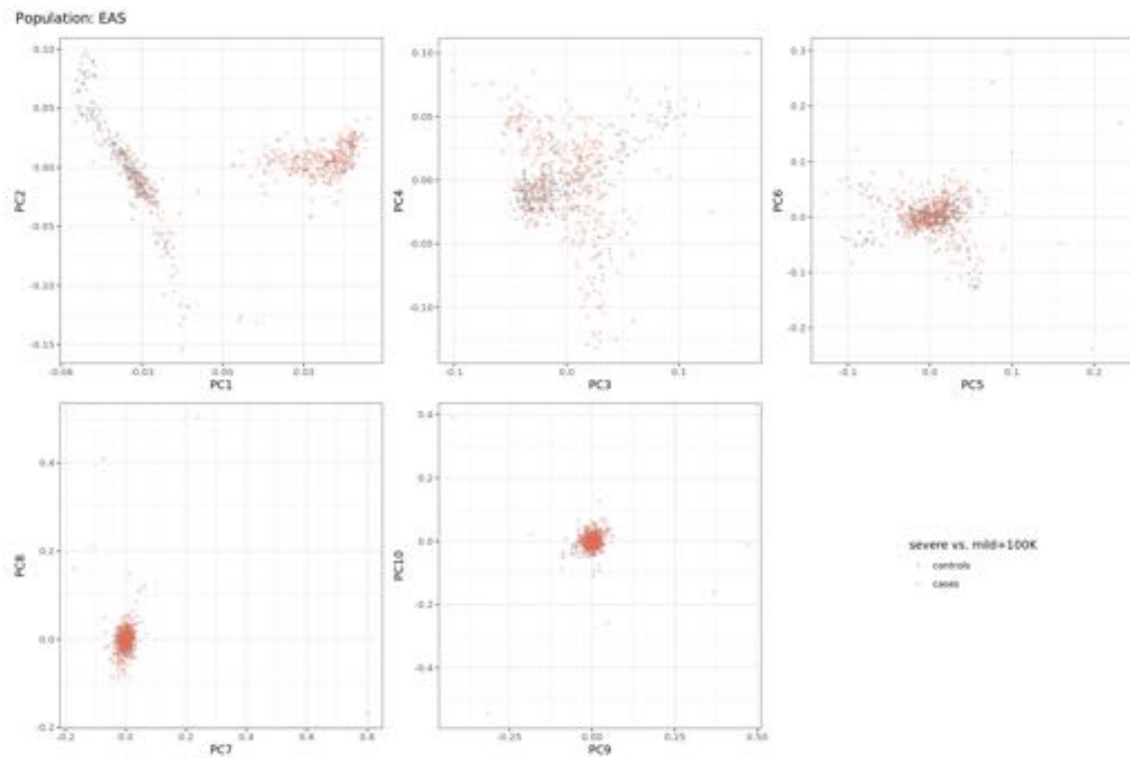

Figure 8: EAS PCs 1-10 for severe (cases) and mild + 100K individuals (controls).

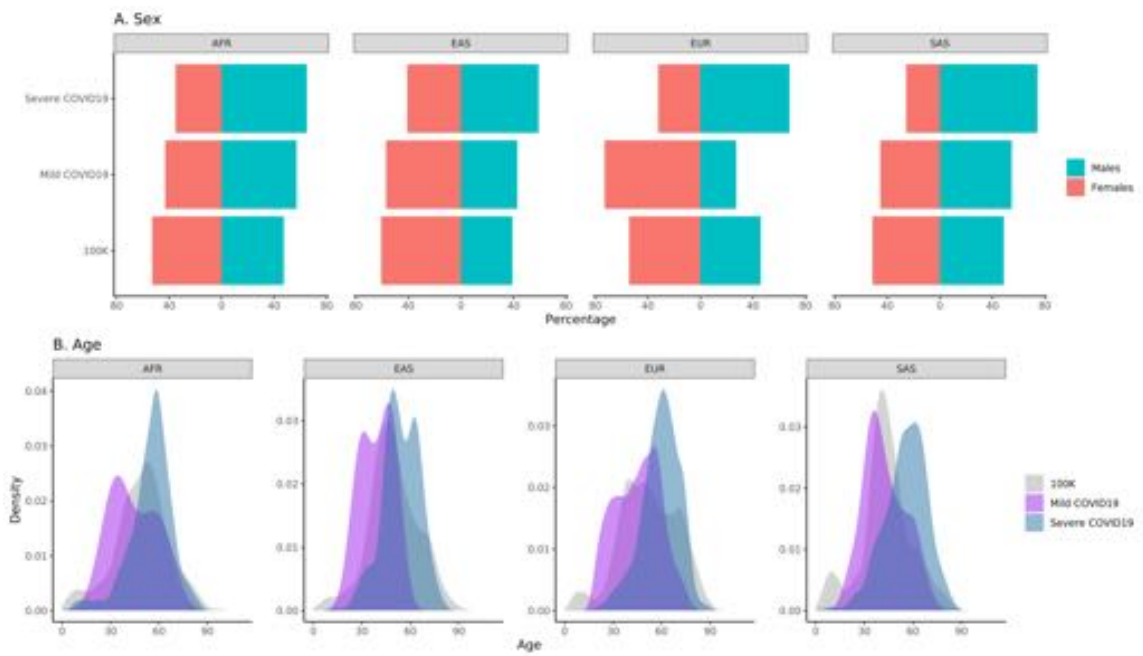

Figure 9: Breakdown of sex and age for severe, mild and 100K cohorts.

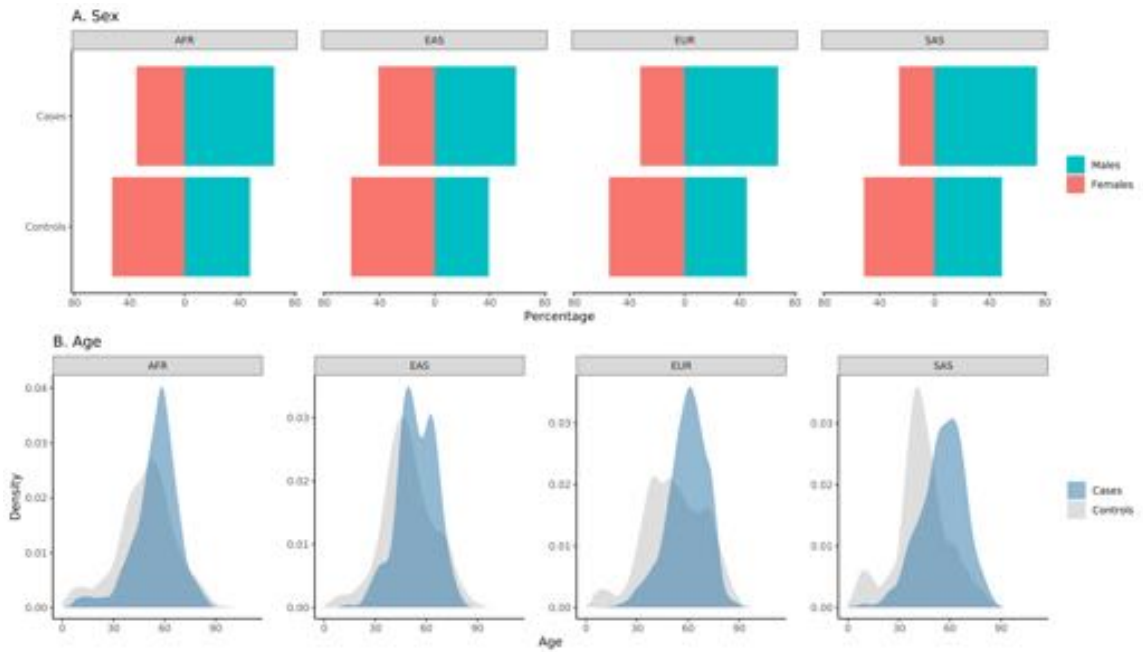

Figure 10: Breakdown of sex and age for cases and controls of the severe (cases) vs. mild+100K (controls) cohorts.

Predicted Ancestry	<i>covid-severe</i>	<i>covid-mild</i>	<i>100K-Genomes (not realigned)</i>	<i>100K-Genomes (realigned)</i>
EUR	5,989	1,507	38,325	3,059
SAS	788	95	3379	319
AFR	440	14	1025	311
EAS	274	14	280	72

Table 2: Breakdown of the cohorts included in this study by predicted ancestry, after sample QC and removal of related individuals.

41 GWAS

42 Per-population GWAS results

Population	No. of ld-pruned variants	Bonferroni-corrected P-value threshold
EUR	2264479	2.2e-08
SAS	2729540	1.8e-08
AFR	5370001	9.3e-09
EAS	1264431	4e-08

Table 3: The Bonferroni-corrected P -values for the per-population GWAS analyses. The P -value significance threshold was calculated by estimating the effective number of tests. After selecting the final filtered set of tested variants for each population, we LD-pruned in a window of 250Kb and $r^2 = 0.8$ with plink 1.9.

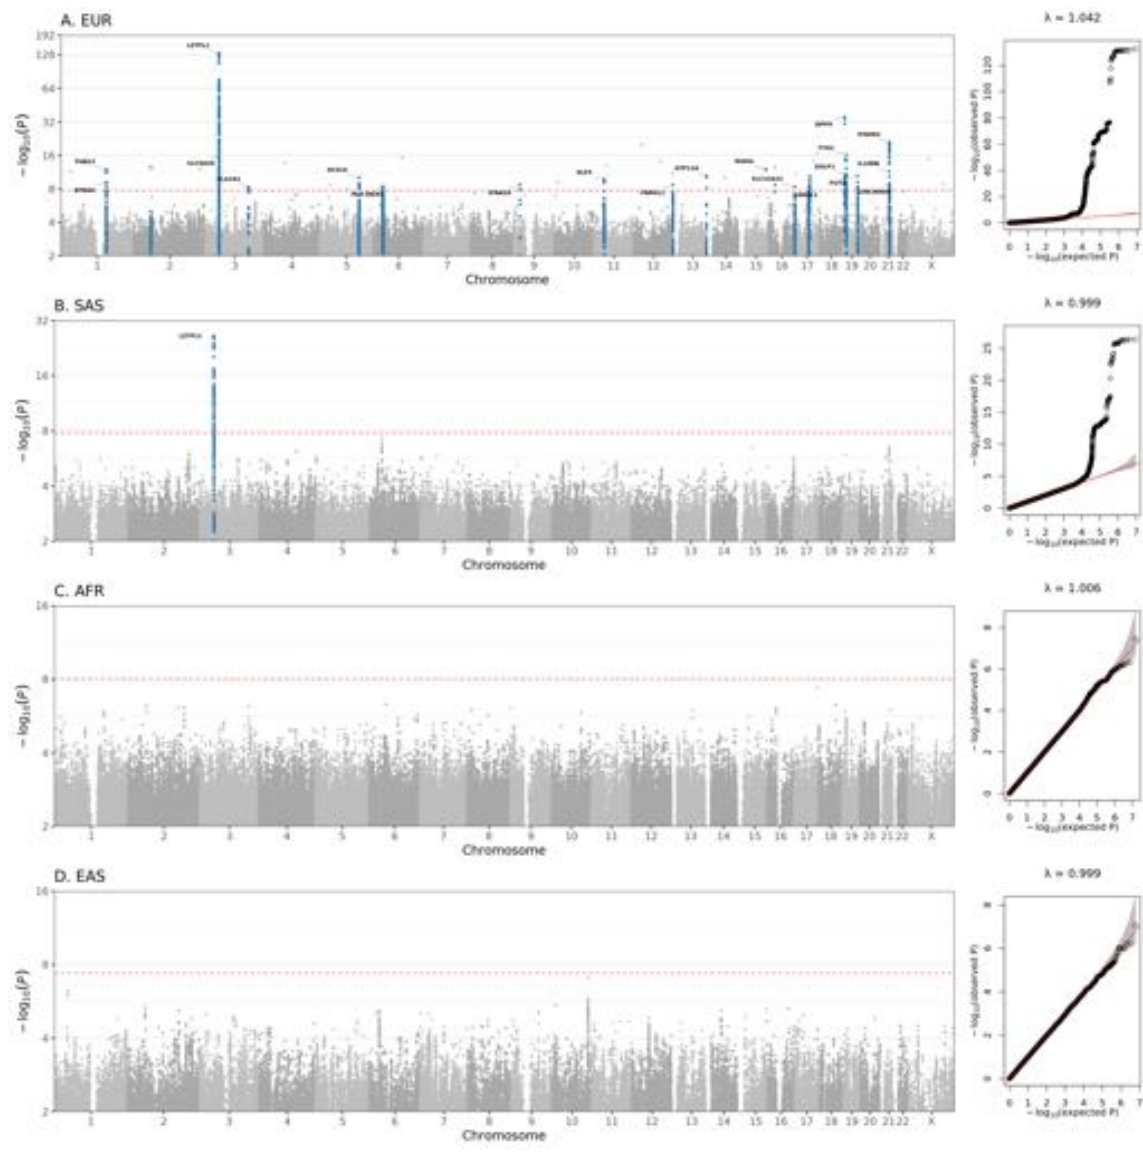

Figure 11: Manhattan plots showing GWAS results for each population cohort. The highlighted results with blue are the variants that are LD clumped ($r^2=0.1$, $P_2=0.01$ in each population) with each lead variant. Red dashed line is the Bonferroni-corrected P -value according to the number of estimated independent tests in each population.

43 LD-based validation of lead GWAS signals

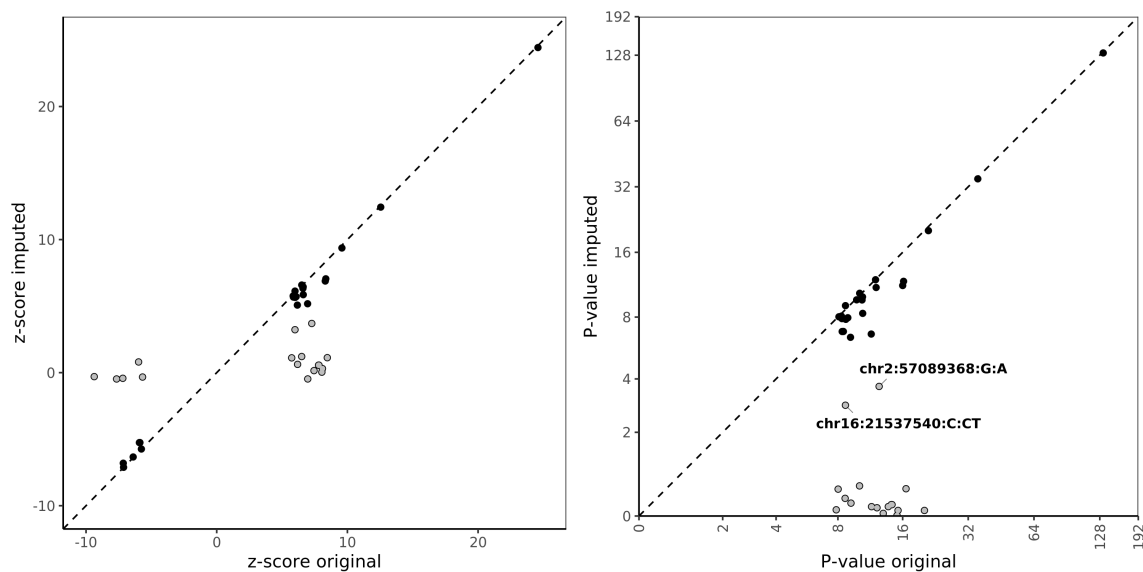

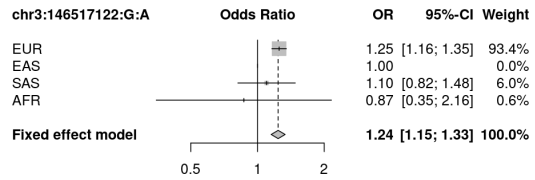

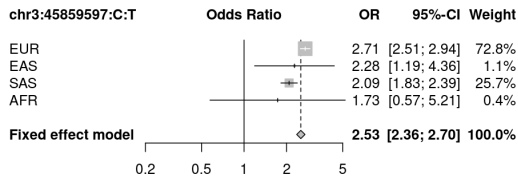

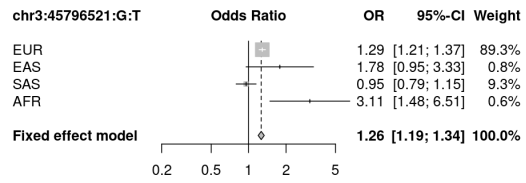

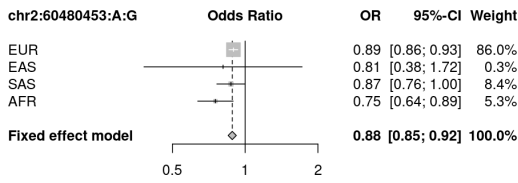

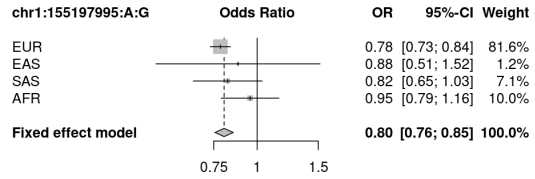

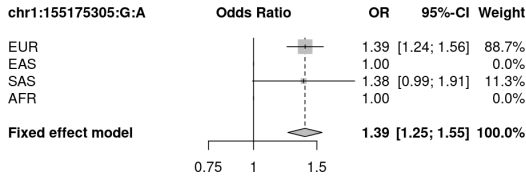

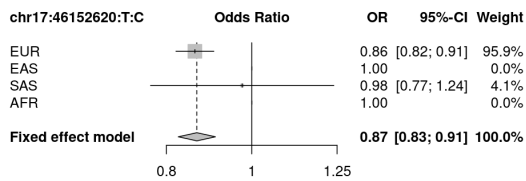

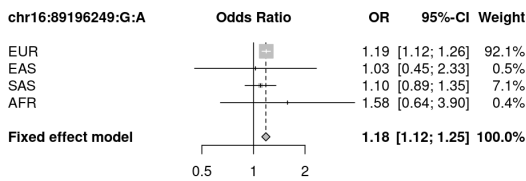

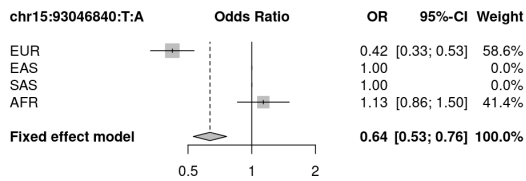

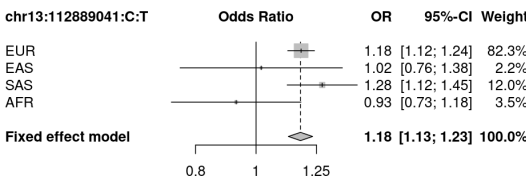

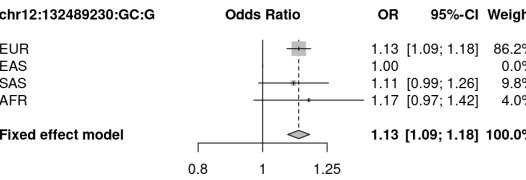

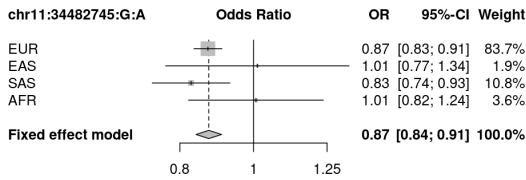

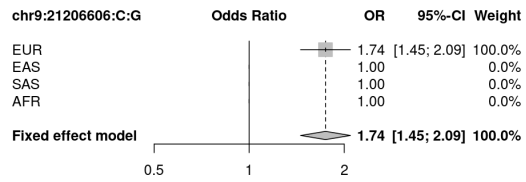

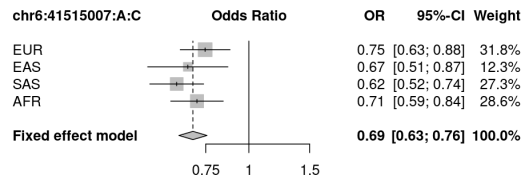

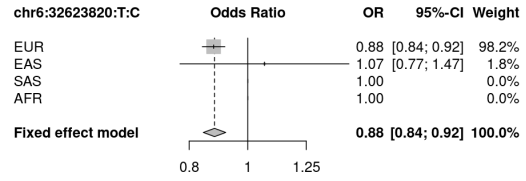

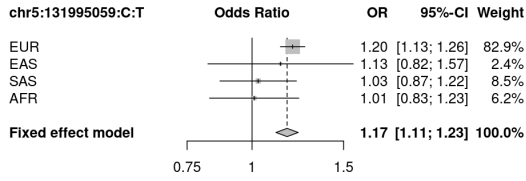

Figure 12: Original and imputed zscores and respective P -values with leave-one procedure for lead variants of the EUR analysis. Variants with low support from neighbouring variants are highlighted with grey.

44 Association signal forest plots

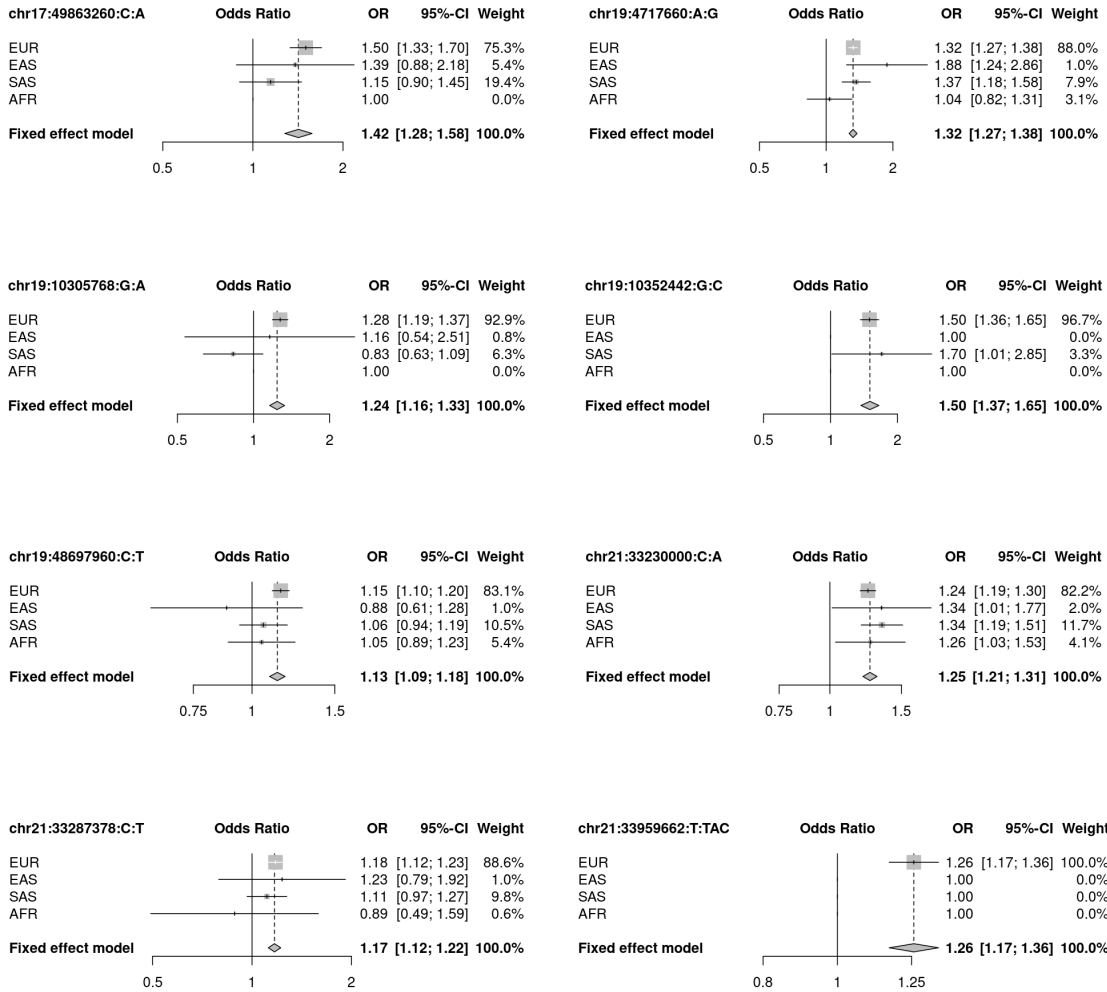

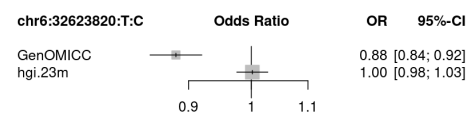

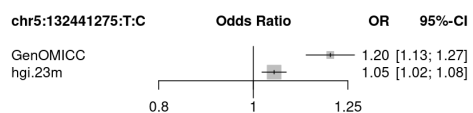

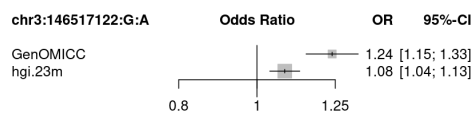

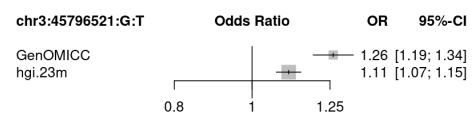

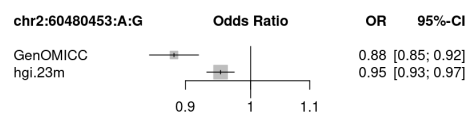

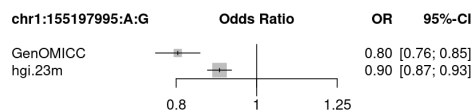

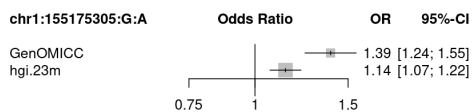

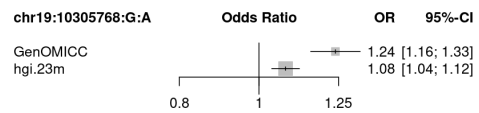

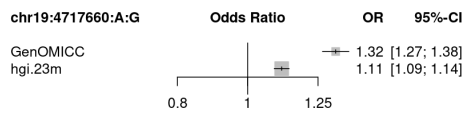

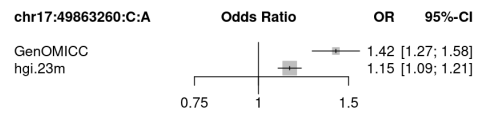

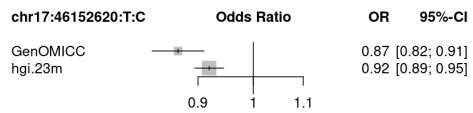

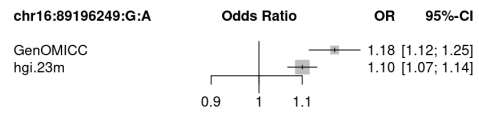

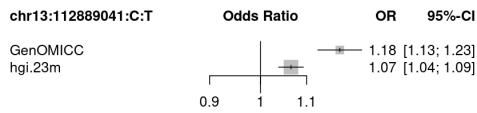

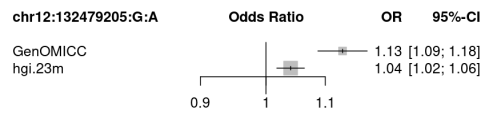

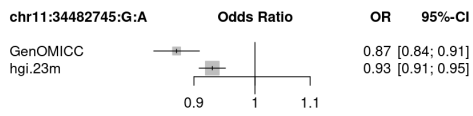

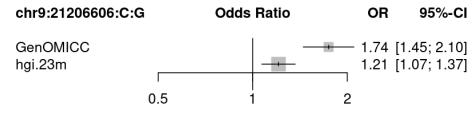

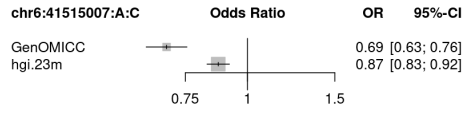

Figure 13: Forest plots for all lead signals.

45 Replication forestplots

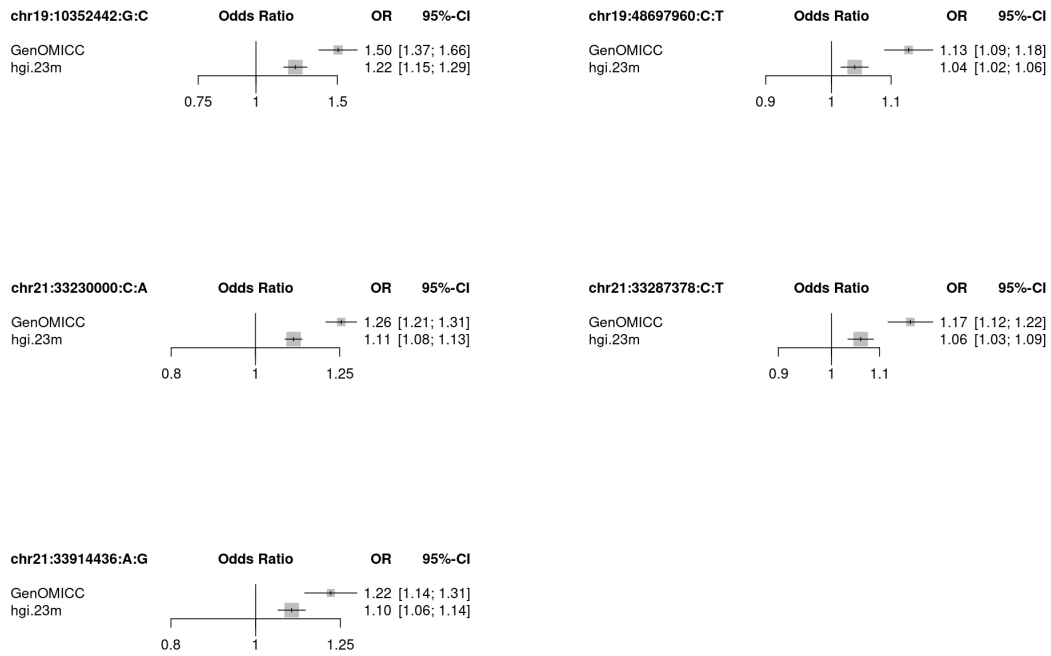

Figure 14: Forest plots comparing the Odds ratios for all the lead signals with a combined meta-analysis of HGI freeze 6 B2 and 23andMe. The HGI summaries were produced with new meta-analysis that removed the GENOMICC cases to ensure statistical independence. The Genomics England 100K participants (i.e, controls) summary data contributed to HGI C2 analysis and not B2 used here.

46 Genetic fine-mapping and colocalisation

47 In the EUR ancestry group, we found two independent signals for the association at 1q22. The lead
48 variant for the first fine-mapped locus is a synonymous variant in *EFNA4* (chr1:155066988:C:T),
49 while the lead variant of the second independent signal (chr1:155197995:A:G) is an intronic variant in
50 *THSB3*, in close proximity to the most significant single-tissue eQTLs for *MUC1* (chr1:155199564:G:T,
51 chr1:155199139:G:A) in GTEx v8, which are also in the same intronic region. Fine mapping the
52 trans-ancestry meta-analysis revealed a third independent signal at this locus, with the lead variant
53 (chr1:155175305:G:A, rs7528026, OR:1.39, 95% CIs:[1.24-1.55]) being in an intron of *TRIM46*. This
54 variant is an sQTL and eQTL for *MUC1* in lung and whole blood tissue, respectively, in GTEx
55 v8¹ (Supplementary File TWAS.xlsx).

56 Meta-analysis across genetically inferred ancestries revealed a novel locus at 2p16.1, with the lead
57 variant (chr2:60480453:A:G, OR:0.88, 95% CIs:[0.85,0.92]) being in an intron of *BCL11A*.

58 We fine-mapped the signal in the 3p21.31 region, first reported by Ellighaus *et al.*,² into two
59 independent associations. The lead variant for the first association is in the 5' UTR region
60 of *SLC6A20* (chr3:45796521:G:T, OR:1.29, 95% CIs:[1.21,1.37]). The second association in the
61 chr3p21.31 region is seen at genome-wide significance in both the EUR and SAS cohorts, with two of
62 the three highest ranked variants in the fine-mapped region in the two populations shared between
63 the two cohorts (chr3:45818159:G:A, chr3:45859597:C:T) and residing in downstream and intronic
64 regions of *LZTFL1*.

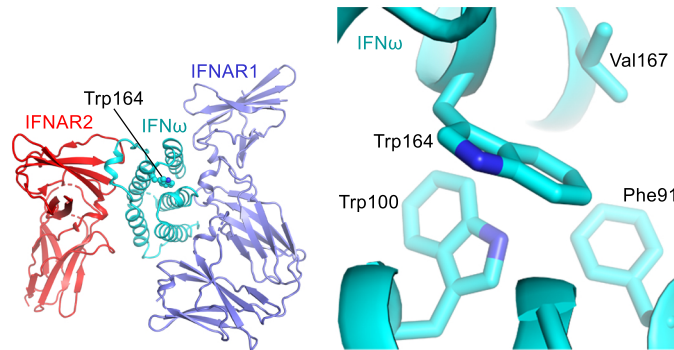

Figure 15: Structural predictions for impact of risk variant on IFNA10

65 The credible set for the 3q24 association included 9 variant and the lead variant (chr3:146517122:G:A,
66 rs343320,p.His262Tyr, OR:1.24, 95% CIs [1.15-1.33]) is a missense variant in *PLSCR1*, predicted to
67 be damaging by CADD (CADD:22.6).

68 At 5q31.1, the lead variant (chr5:131995059:C:T, rs56162149, OR:1.17, 95% CIs:[1.11,1.23]) is in an
69 intron of *ACSL6*. The credible set for this locus contains 33 variants that span 484 kb including
70 variants in genes *CSF2* and *IRF1-AS1*, with chr5:132075767:T:C being a missense variant in *CSF2*
71 and chr5:131991772:C:G being missense in *ACSL6* and only intronic variants for *IRF1-AS1*.

72 The previously reported signal at 6p21.1, linked to *FOXP4*³, is stronger in the SAS cohort but has
73 a consistent effect across ancestries ($P_{het}=0.49$).

74 We fine mapped the signal at 9p21.3 to three variants with lead variant (chr9:21206606:C:G,
75 rs28368148,p.Trp164Cys, OR:1.74, 95% CIs [1.45-2.09]) being a missense variant in IFNA10 that is
76 predicted to be damaging by CADD (CADD:23.9) with potential functional impact Supplementary
77 Figure 15.

78 The signal in the 11p13 region was fine-mapped to four variants (lead variant chr11:34482745:G:A,
79 rs61882275, OR:0.87, 95% CIs:[0.84-0.91]), all four of which are in an intron of *ELF5*.

80 The credible set for the signal in the 12q24.33 region includes 24 variants spanning 95 kb, of which
81 the lead (chr12:132489230:GC:G, rs56106917, OR:1.13, 95% CIs:[1.09-1.18]) lies upsdream *FBRSL1*.

82 The signal at 13q34 was fine-mapped to four variants, with lead variant (13:112889041:C:T, rs9577175,
83 OR:1.18, 95% CIs [1.12-1.24]) lying downstream of *ATP11A* and upstream of *MCF2L* genes.

84 The association at 15q26.1 was fine mapped to two variants with lead variant (chr15:93046840:T:A,
85 rs4424872, OR: 2.37, 95% CIs:[1.87-3.01] in an intron of *RGMA*. This a low frequency (allele
86 frequency <1%) variant that was not replicated due to lack of coverage in the available replication
87 data and further validation in an independent dataset is recommended.

88 The credible set for the association with lead variant at chr17:46152620:T:C (rs2532300, OR:1.16,
89 95% CIs:[1.10,1.22]) includes 1430 variants and spans 658 kb, indicating an association with the
90 known inversion haplotype at 17q21.31⁴.

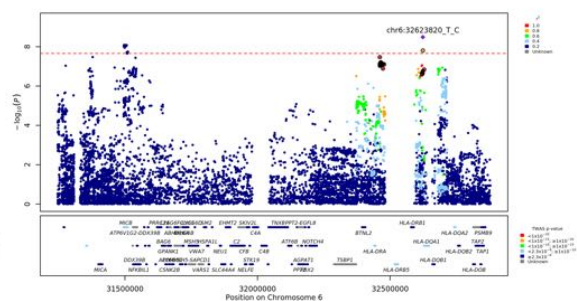

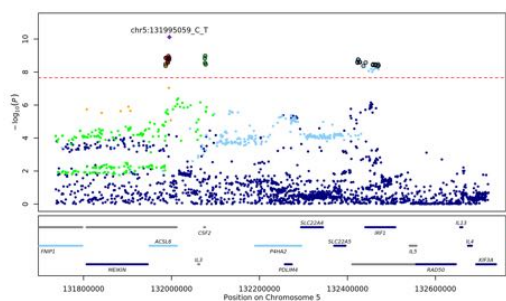

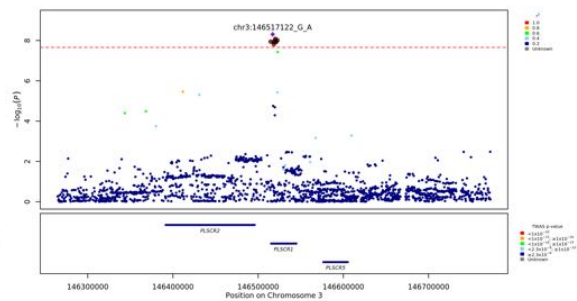

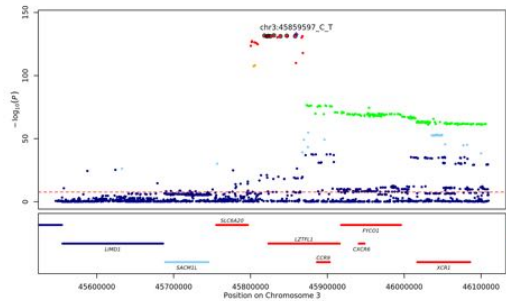

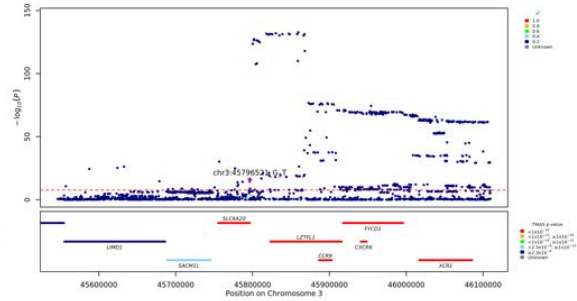

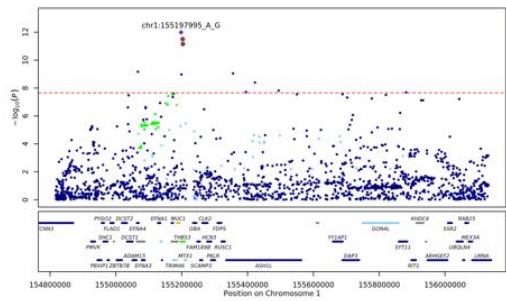

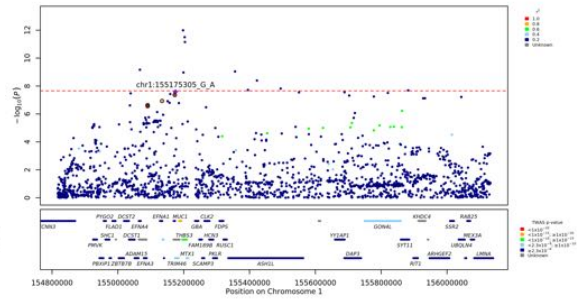

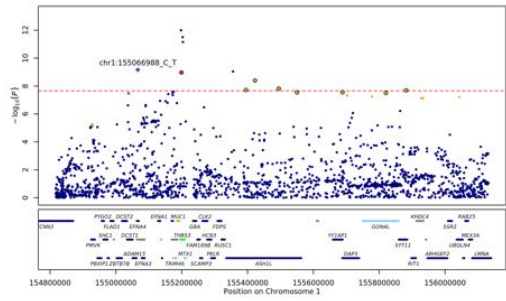

91 We fine mapped the signal at 17q21.33 to five variants, with lead variant (chr17:49863260:C:A,
92 rs3848456, OR:1.5, 95% CIs:[1.33-1.70] residing in a regulatory element (ENSR00001010694) 15.5
93 kb upstream of the *TAC4* gene.

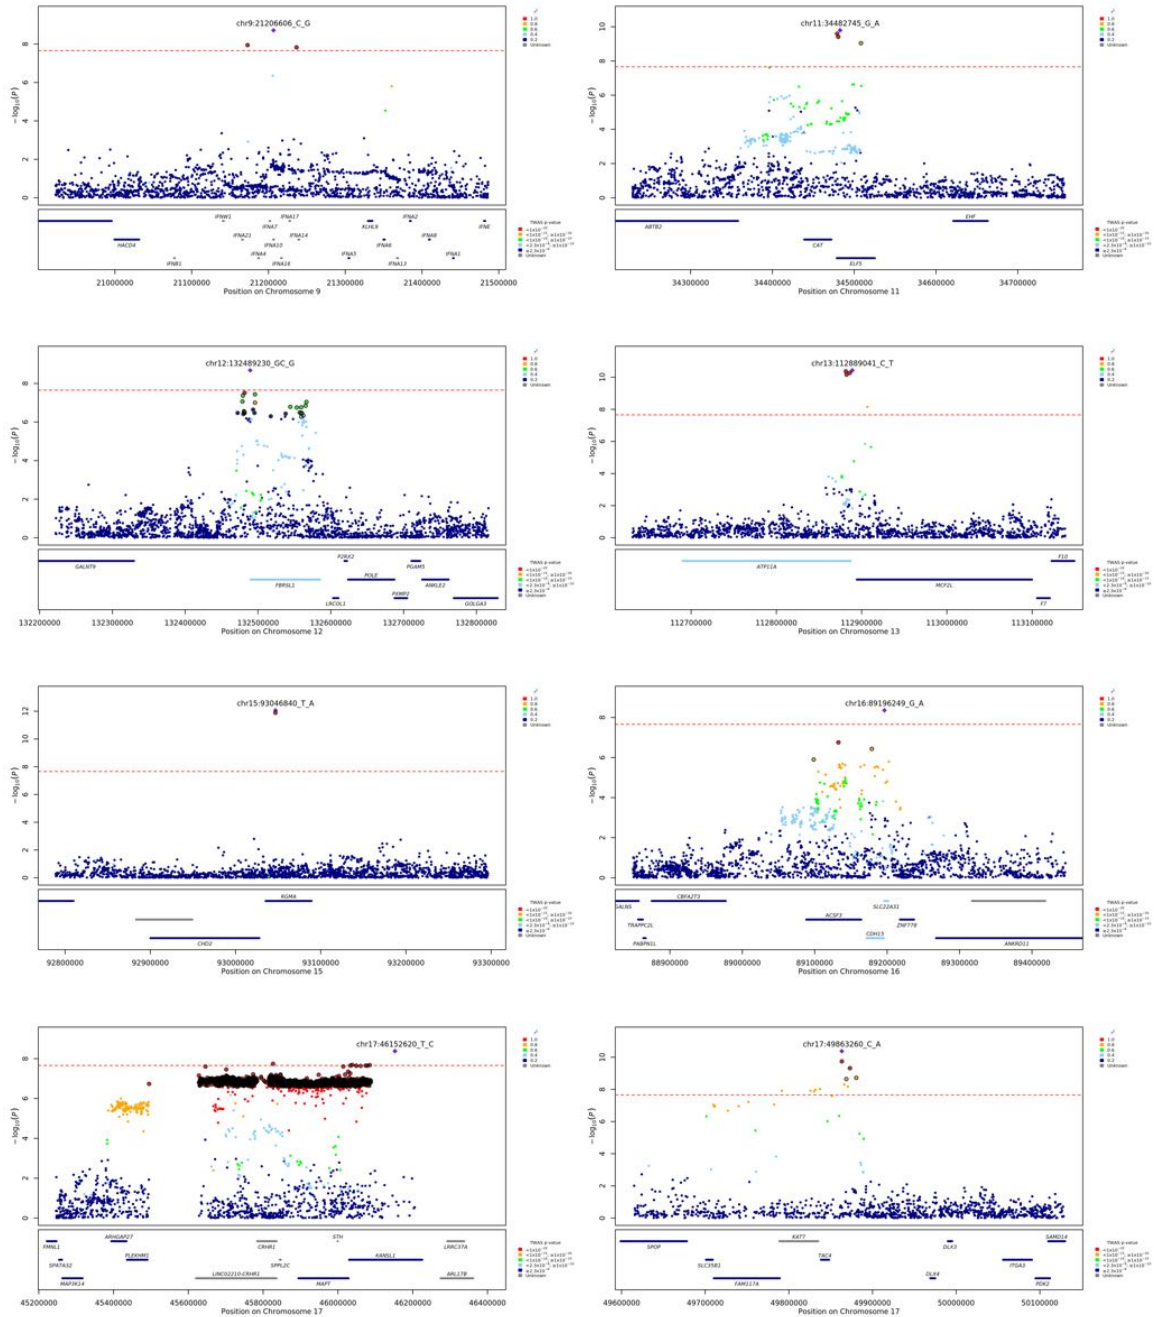

94 In the 19p13.3 region, which we reported in 2020,⁵ we fine-mapped the signal to a single variant in
95 *DPP9* (chr19:4717660:A:G). This variant is a missense variant in transcript ENST00000599248 but
96 intronic in other transcripts including the MANE transcript (ENST00000262960.14).

97 In the 19p13.2 region, where we previously reported a variant associated with *TYK2*,⁵ we find two
98 independent signals, one of which is a damaging missense variant in *TYK2*, chr19:10352442:G:C
99 (rs34536443, OR:1.50, 95% CIs:[1.36,1.65], CADD=25.1), and the second is an intronic variant of
100 *ZGLP1* (19:10305768:G:A, rs73510898, OR:1.28, 95% CIs:[1.19,1.37]).

101 The signal at 19q13.33 was fine-mapped to ten variants, with the lead variant (chr19:48697960:C:T,
102 rs368565, OR:1.15, 95% CIs [1.1-1.2]) in an intron of *FUT2* and variant chr19:48705753:T:C (rs503279)
103 being in the 3' UTR of the MANE transcript for this gene.

104 In the 21q22.11 region, we described previously,⁵ fine-mapping revealed three independent signals, for
105 which the lead variants reside in the 5' UTR of *IFNAR2* (chr21:33230000:C:G,rs17860115, OR:1.24,
106 95% CIs:[1.19-1.30], CADD=10.1), an intronic region of *IL10RB* (chr21:33287378:C:T, rs8178521,
107 OR:1.18, 95% CIs:[1.12,1.23]) and in a downstream long non-coding RNA (chr21:33959662:T:TAC,
108 rs35370143, OR:1.26, 95% CIs:[1.17,1.36]).

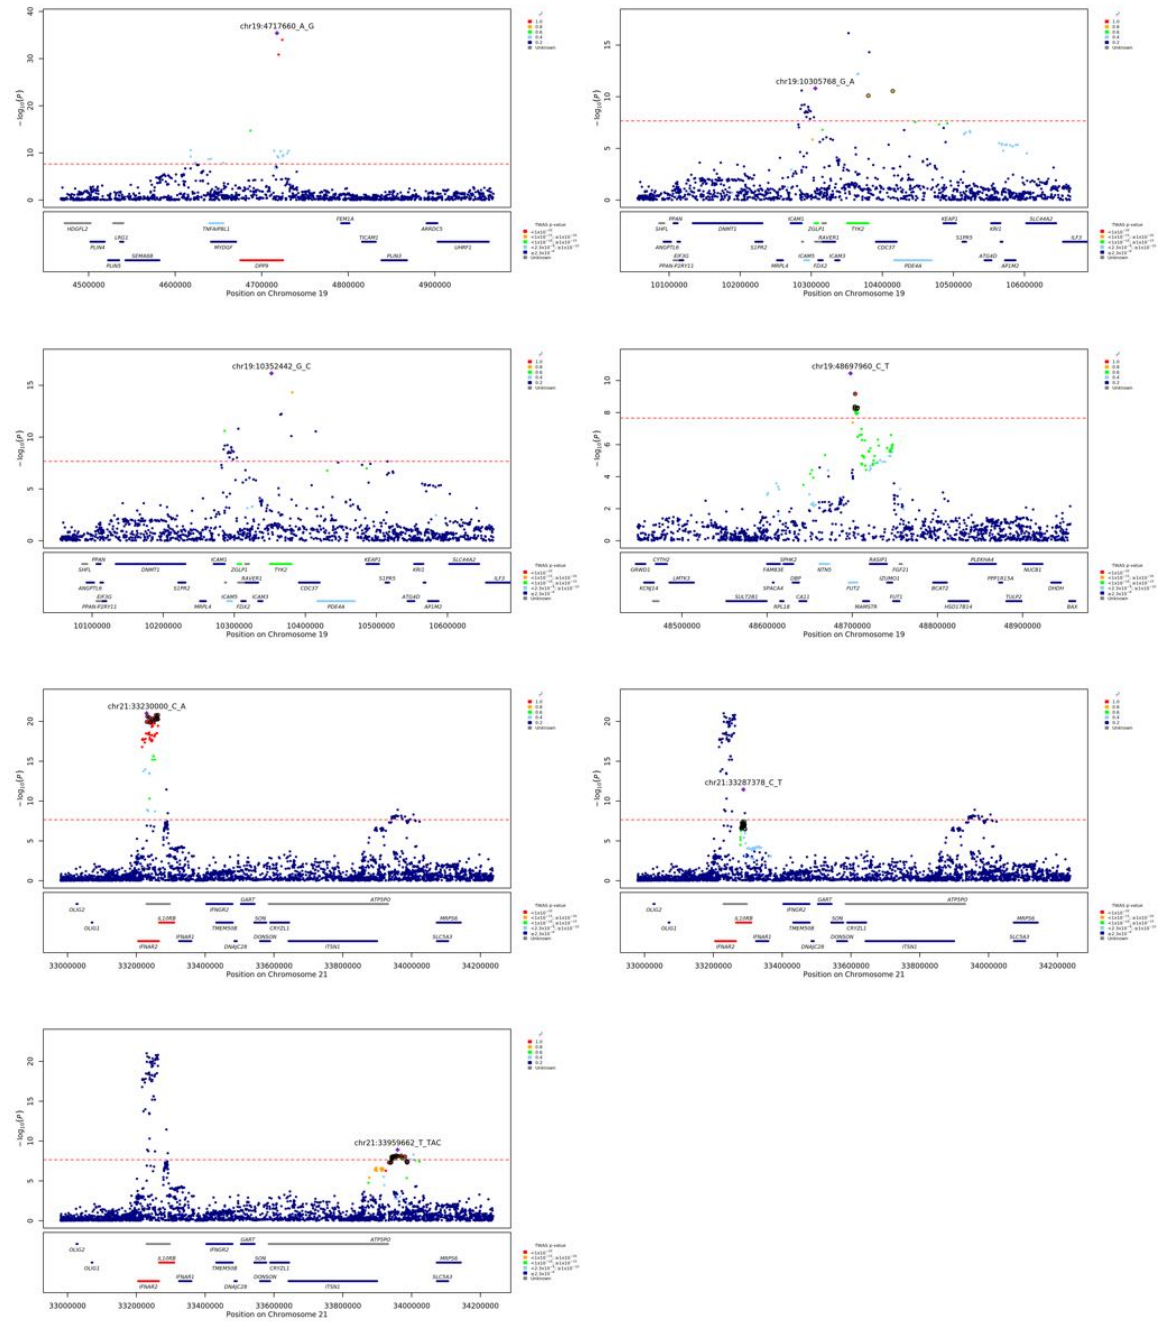

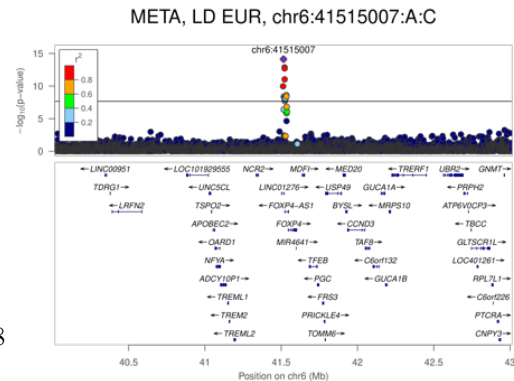

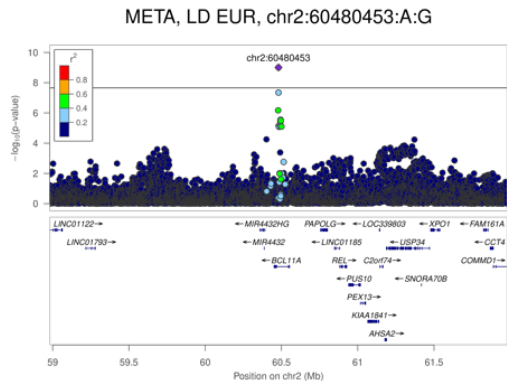

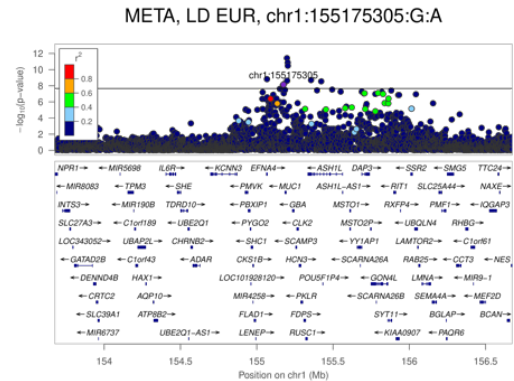

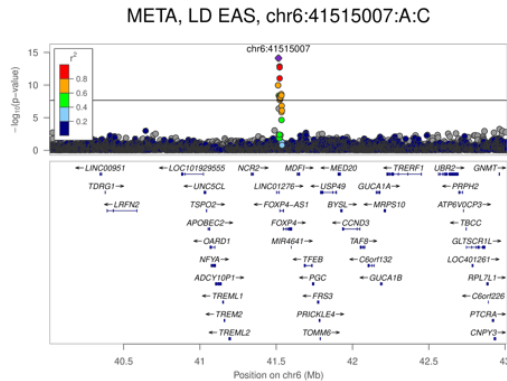

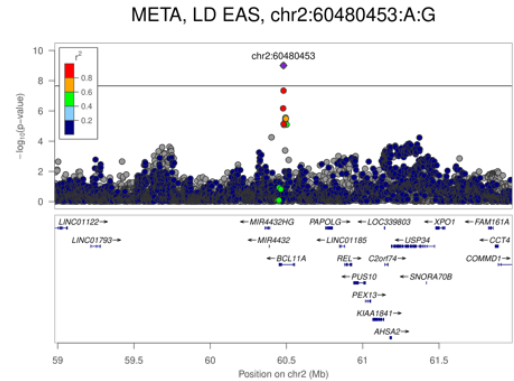

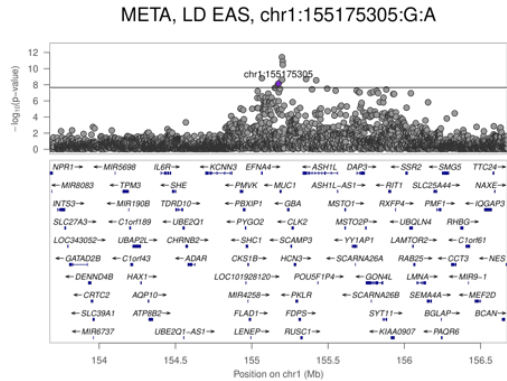

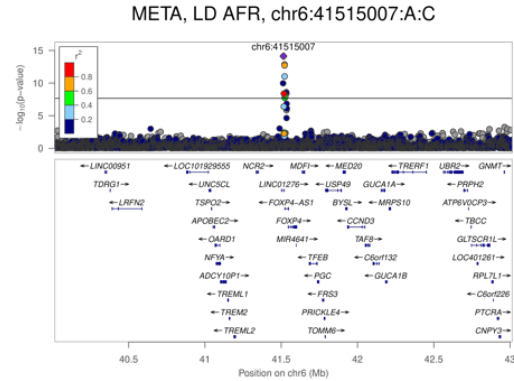

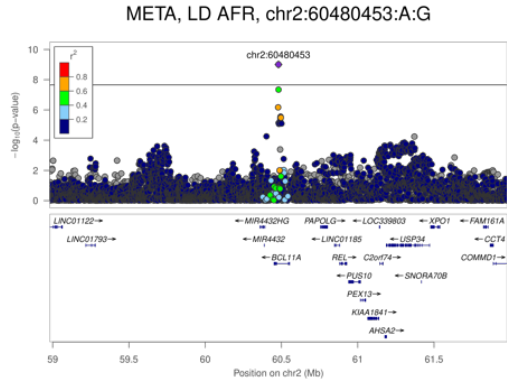

Figure 16: Locuszoom figures for the signals found in the per-population analyses. Upper panels show lead signals and LD calculated in EUR with all other loci in the window shown. Credible sets for each displayed signal that were inferred with susieR are displayed with outline black circles. On the bottom panels an hg38 gene track is displayed with colors matching significance from the metaTWAS analysis in discrete bins shown.

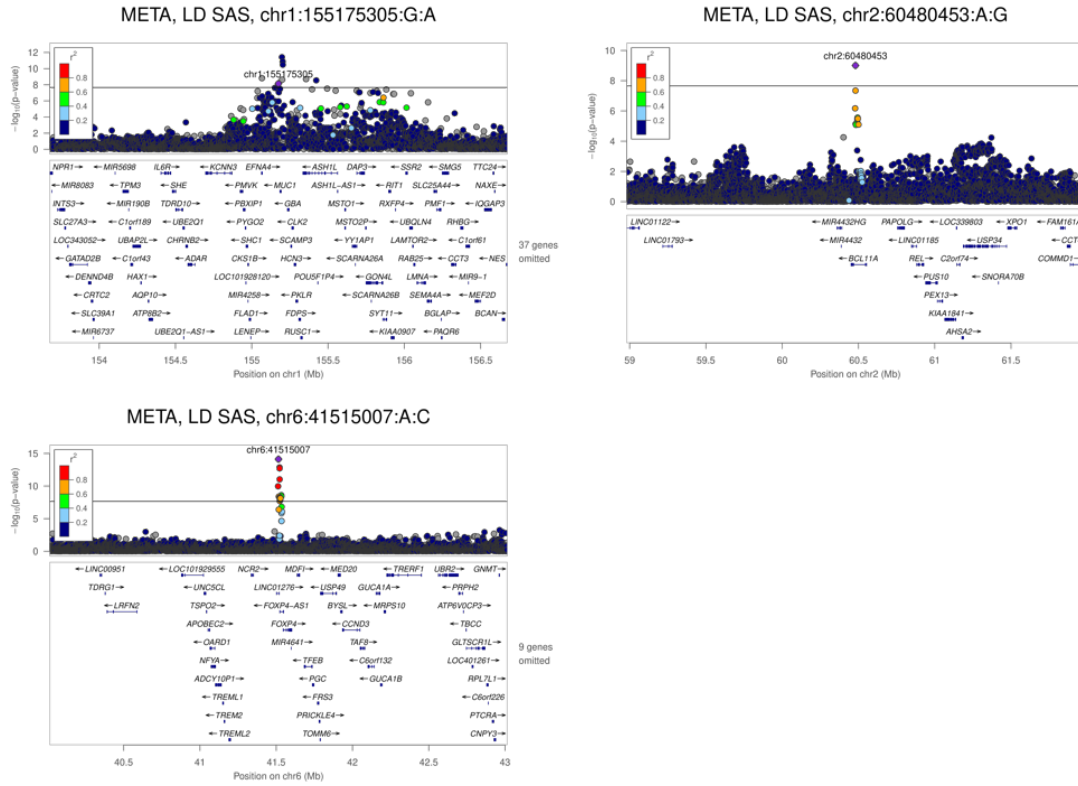

Figure 17: Locuszoom figures for the transethnic meta-analysis signals with different panels for LD calculated in the four populations of this study (AFR, EAS, EUR, SAS).

109 **Stratified analysis**

110 We performed sex- (< 60 vs. ≥ 60) and age-stratified analyses. We did not obtain significant
111 evidence for sex- specific effects (Supplementary Figure 18). The locus at chr3:45801750:G:A
112 (rs13071258) in the European population had a significantly stronger effect in the younger age group
113 ($OR = 3.34, 95\%CI = 2.98 - 3.75$ vs. $OR = 2.1, 95\%CI = 1.88 - 2.34$).

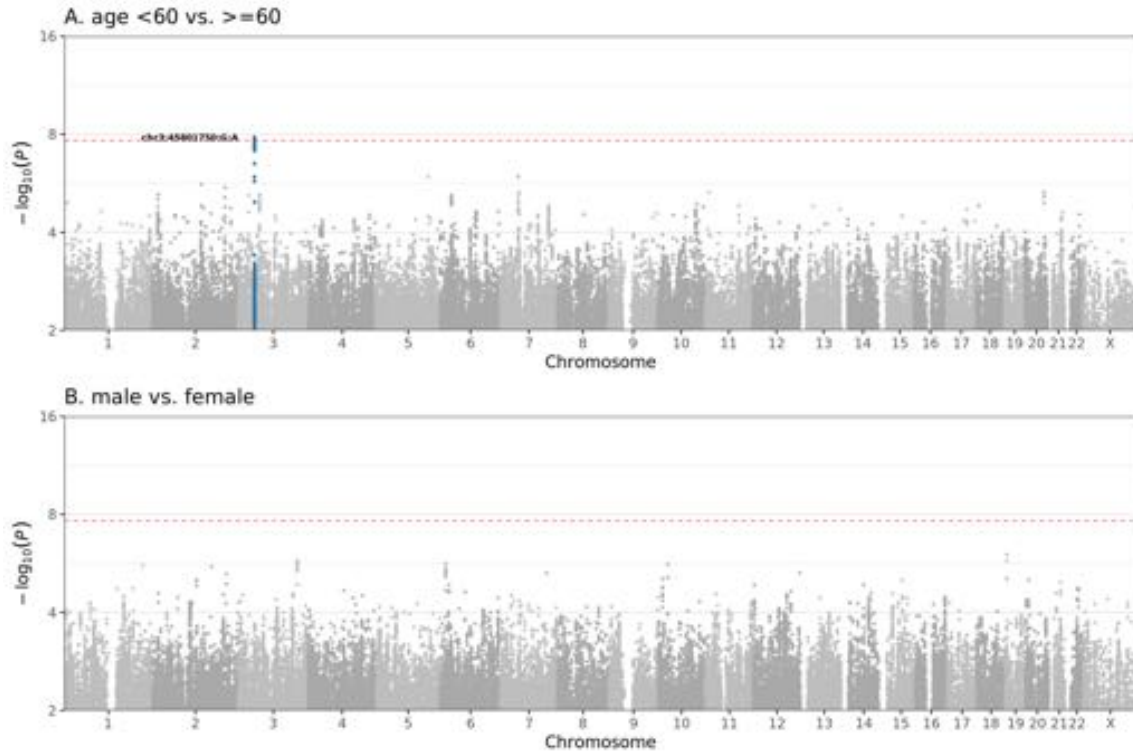

Figure 18: Manhattan plot for t -test P -values obtained from comparison of stratified GWAS analyses by age and sex. GWAS analyses were run for stratified subsets of the severe vs. mild+100K analysis for individuals with (A) age >60 vs. ≥60 and (B) males vs. females. For each analysis we then performed a t -test comparing between-group effect sizes per variant. Red dashed line corresponds to Bonferroni-corrected P -value = 2×10^{-8} .

114 TWAS

115 eQTL TWAS

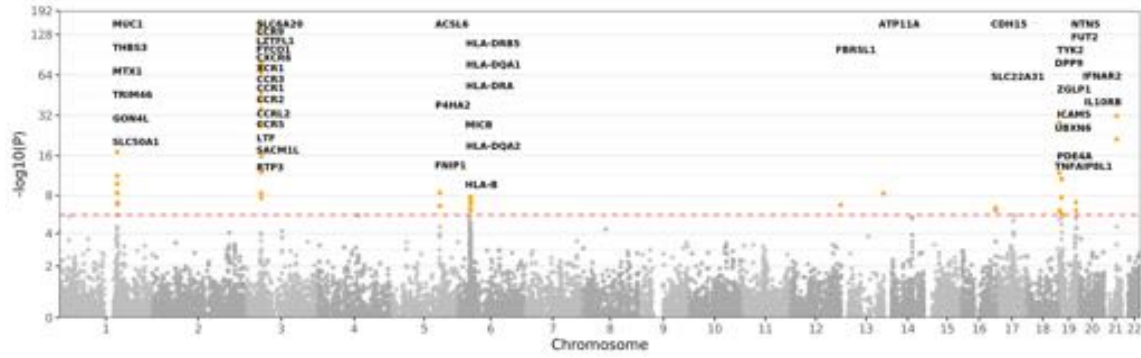

Figure 19: TWAS results from meta-analysis of eQTL models from all tissues in GTExv8. All significant genes at $P < 2.3 \times 10^{-6}$ (red dashed line) are annotated.

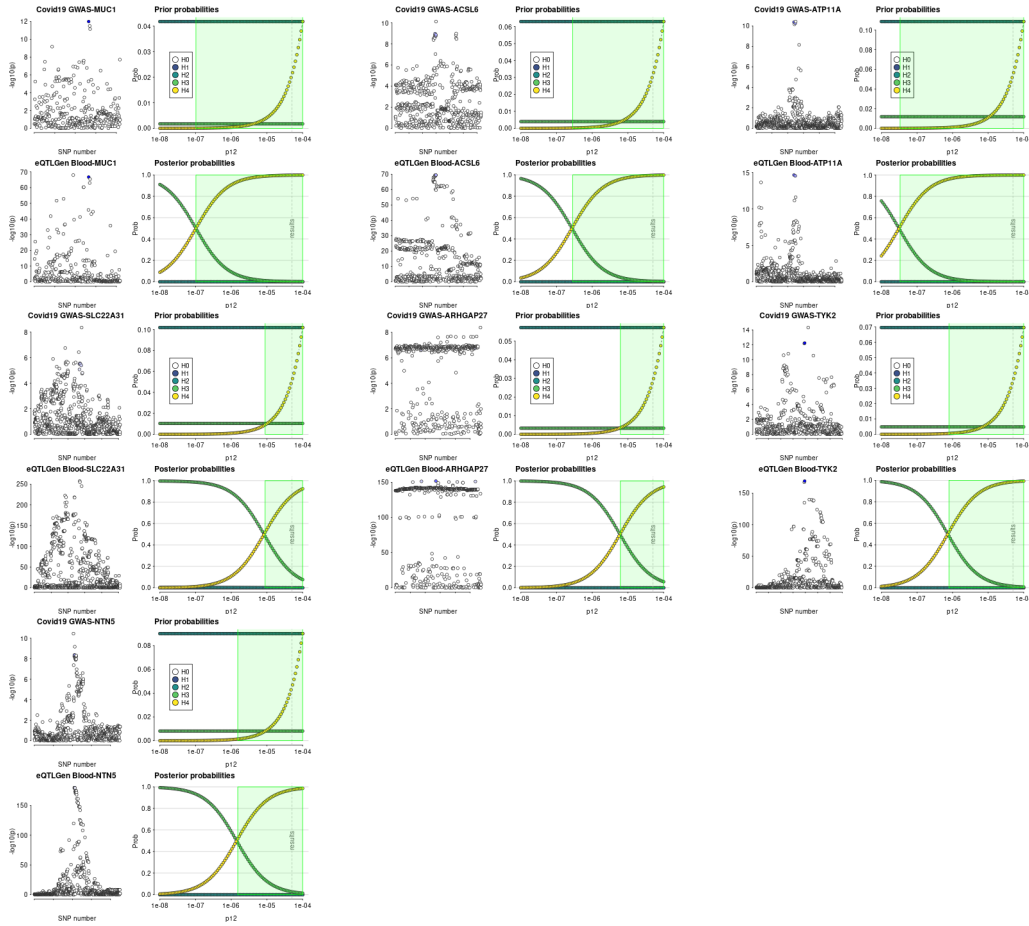

Figure 20: Sensitivity analysis for colocalisation of TWAS-significant loci in blood (eQTLgen data) with GWAS signals. Evidence for the following hypotheses is plotted across a range of prior probabilities: H0 - neither trait has a genetic association in the region; H1 - only trait 1 has a genetic association in the region; H2 - only trait 2 has a genetic association in the region; H3 - both traits are associated, but with different causal variants; H4 - both traits are associated and share a single causal variant.

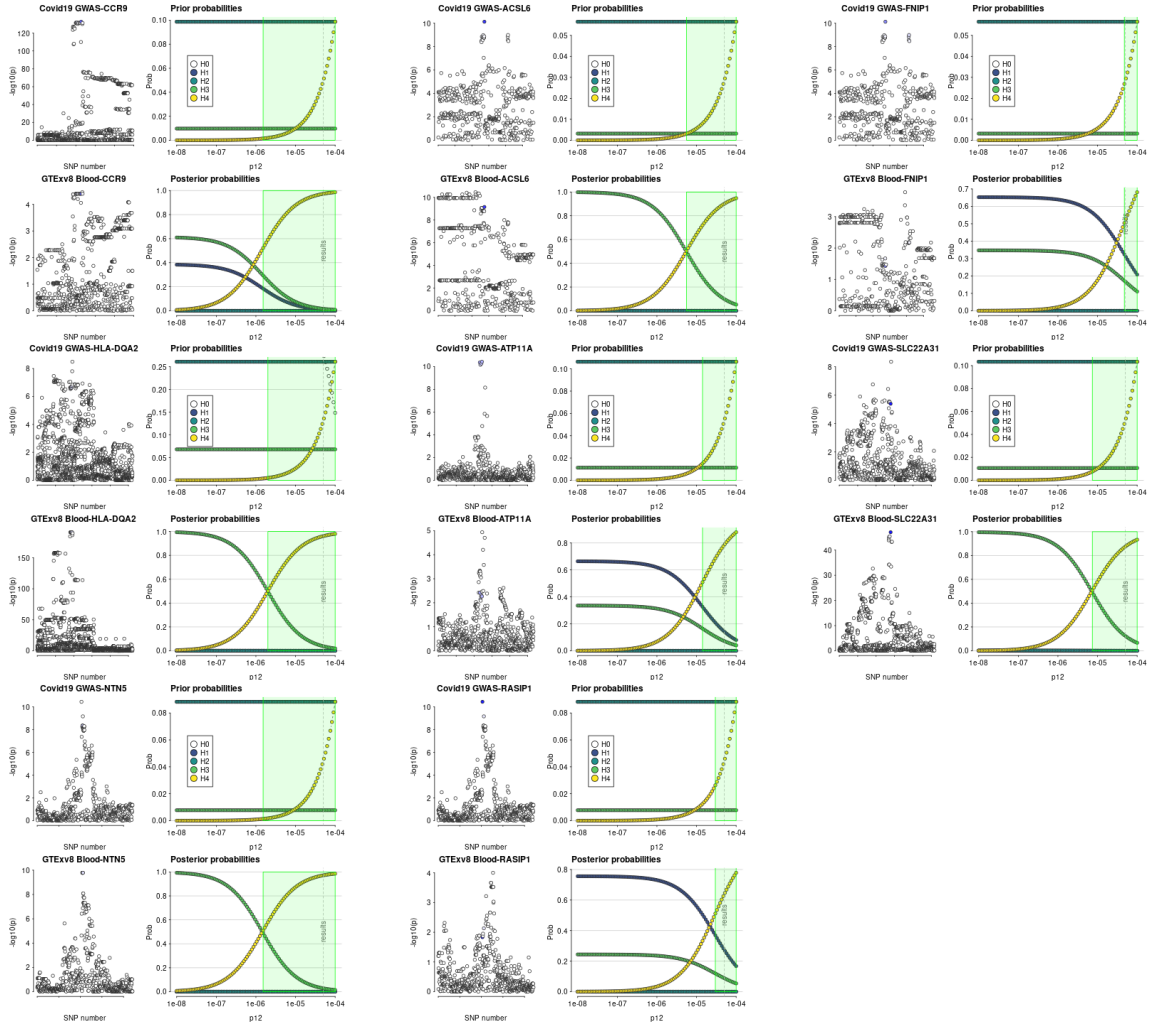

Figure 21: Sensitivity analysis for colocalisation of TWAS-significant loci in blood (GTExv8 data) with GWAS signals. Evidence for the following hypotheses is plotted across a range of prior probabilities: H0 - neither trait has a genetic association in the region; H1 - only trait 1 has a genetic association in the region; H2 - only trait 2 has a genetic association in the region; H3 - both traits are associated, but with different causal variants; H4 - both traits are associated and share a single causal variant.

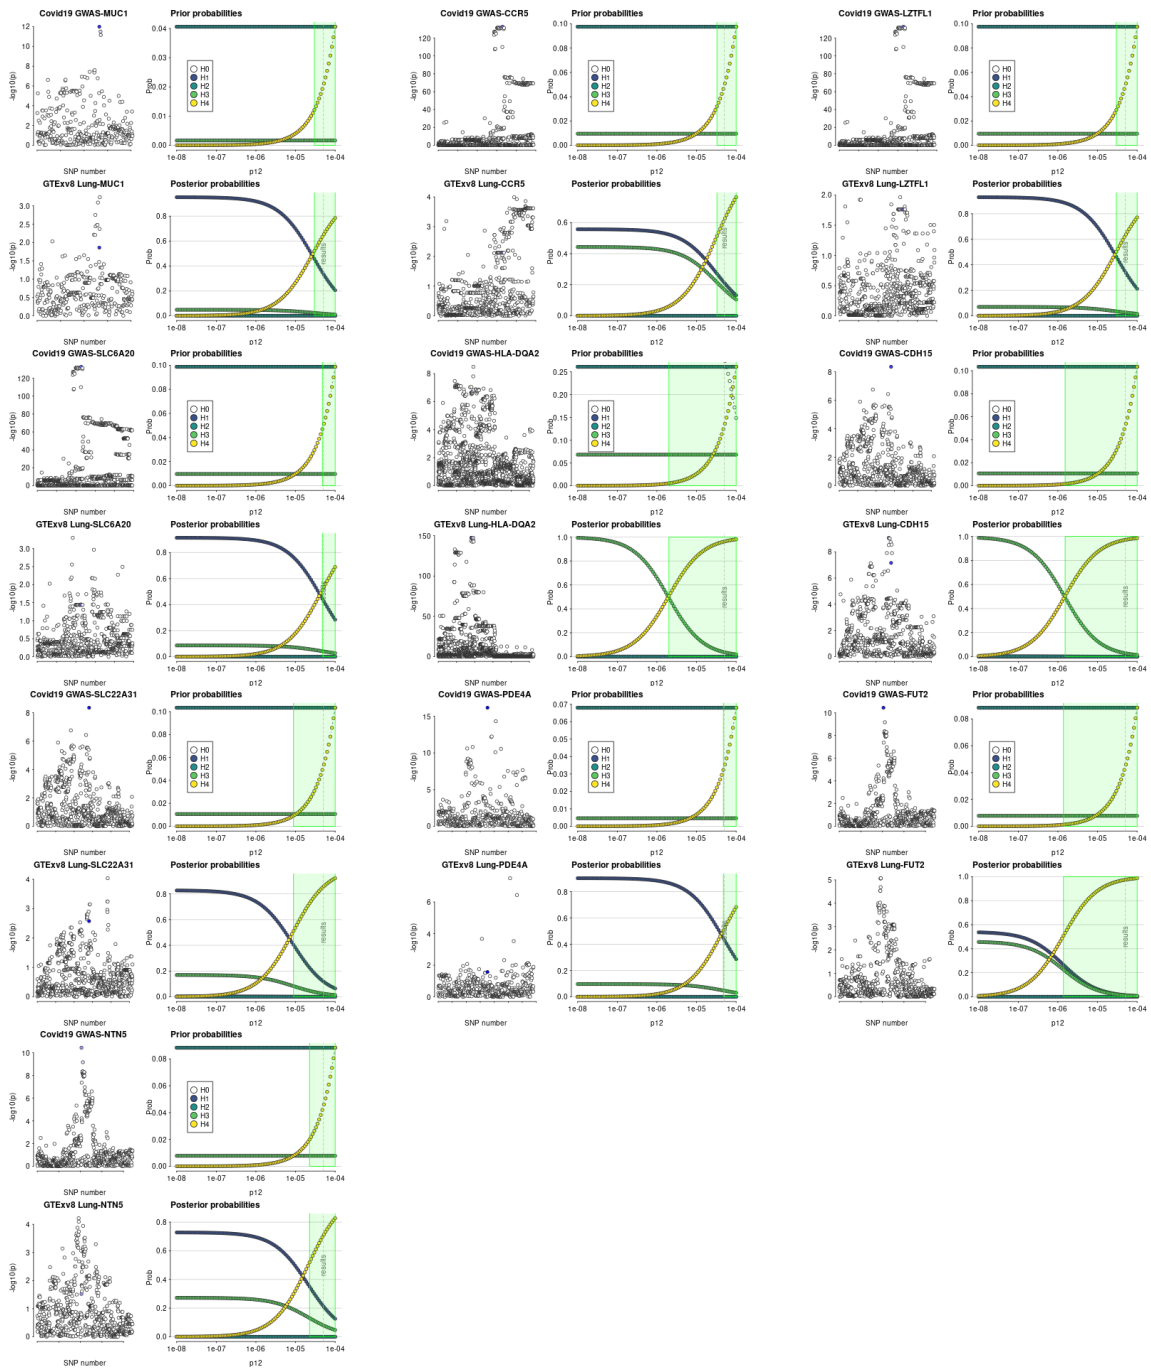

Figure 22: Sensitivity analysis for colocalisation of TWAS-significant loci in lung (GTExv8 data) with GWAS signals. Evidence for the following hypotheses is plotted across a range of prior probabilities: H0 - neither trait has a genetic association in the region; H1 - only trait 1 has a genetic association in the region; H2 - only trait 2 has a genetic association in the region; H3 - both traits are associated, but with different causal variants; H4 - both traits are associated and share a single causal variant.

117 **Aggregate variant testing (AVT)**

118 Aggregate variant testing on aggCOVID_v4.2 was performed using SKAT-O as implemented in
119 SAIGE-GENE v0.44.5⁶. Variant and sample QC for the preparation of the aggregate files has been
120 described elsewhere. In addition, the following filters were applied to the masked aggregate dataset:

- 121 • Bi-allelic SNPs only
- 122 • Minor allele frequency < 0.005
- 123 • Site wide missingness < 0.05
- 124 • Differential missingness between cases and controls, mid-p value < 10⁻⁵

125 All the variants in the dataset were annotated using VEP v99.

126 **Masks and Model**

127 Two functional annotation masks were applied on top of the filters detailed. The first is a strict
128 putative loss of function (*pLoF*) filter, where only variants that are annotated by Loftee as high
129 confidence loss of function are included. The second is a more lenient filter (*missense*) where all
130 variants from the strict filter are included, together with all variants that have a consequence of
131 missense or worse as annotated by VEP, with a CADD_PHRED score of ≥ 10 (CADD version 1.5).
132 The covariates used in the model were the same as for the single variant analysis: *sex*, *age*, *age*²,
133 *age * sex* and 20 (population-specific) principal components generated from common variants (MAF
134 $\geq 5\%$).

135 The tests were run separately by genetically predicted ancestry, on all protein-coding genes as
136 annotated by Ensembl.

137 **AVT results**

138 Supplementary table 4 shows the number of tested genes per mask per predicted ancestry. These
139 numbers were used to apply a Bonferonni correction on the SKAT-O *P*-values from SAIGE-GENE
140 on a per population basis. The *P*-value thresholds for gene-wide significance were taken as $0.05/n * 2$,
141 with *n* being the number of tested genes in that population, divided by 2 (the number of masks
142 used). This makes the assumption that each gene was tested by both masks, which is conservative
143 for the missense threshold.

Cohort	Tested genes, pLoF mask	<i>P</i> -value threshold, pLoF mask	Tested genes, missense mask	<i>P</i> -value threshold, missense mask
EUR	7,352	3.4e-06	18,631	1.3e-06
SAS	1,435	1.7e-05	17,291	1.4e-06
AFR	763	3.3e-05	16,125	1.6e-06
EAS	265	9.4e-05	12,519	2.0e-06

Table 4: Number of tested genes per mask per predicted ancestry, with *P*-values used to assess gene-wide significance.

144 No significant associations were found across any of the populations. Supplementary figure 23 shows
145 the Manhattan and Q-Q plots for each predicted ancestry using the *pLoF* mask, and supplementary

146 figure 24 shows the Manhattan and Q-Q plots for each predicted ancestry using the *missense* mask.
 147 Supplementary File AVTsuppinfo.xlsx, sheet A and sheet B, show the top ten genes by *P*-value for
 148 each predicted ancestry and all combined ancestries, respectively.

149 Supplementary File AVTsuppinfo.xlsx, sheet C, shows the top genes that were highlighted as part of
 150 the GWAS analysis, ranked by p value per predicted ancestry. Supplementary File AVTsuppinfo.xlsx,
 151 sheet D shows the SKAT-O *P*-values for the 13 genes involved in the regulation of type I and III
 152 interferon immunity that were implicated in severe COVID-19 pneumonia⁷, ranked by p value per
 153 predicted ancestry.

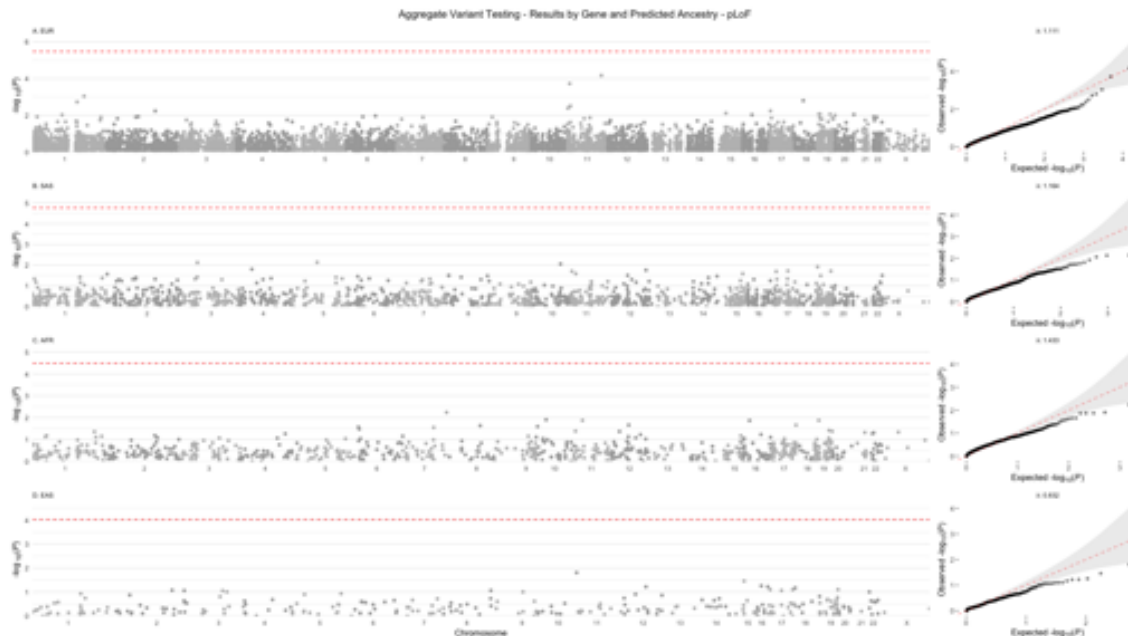

Figure 23: Gene-level manhattan and Q-Q plots per predicted ancestry for the *pLof* mask. Each point in the manhattan plot represents a gene. Panels from top to bottom are for EUR (A), SAS (B), AFR (C) and EAS (D). The red dashed lines indicate Bonferonni corrected "gene-wide" *P*-values (see Table 4).

154 HLA Inference and Association Tests

155 HLA imputation using HIBAG

156 HLA types were imputed at two field (4-digit) resolution for all samples within aggV2 and ag-
 157 gCOVID_v4.2 for the following seven loci: HLA-A, HLA-C, HLA-B, HLA-DRB1, HLA-DQA1,
 158 HLA-DQB1, and HLA-DPB1 using the HIBAG package in R⁸. We used ancestry specific pre-fit
 159 classifiers trained on the Illumina 1M Duo genotyping array on individuals of either European,
 160 Asian, and African ancestry dependent on the assigned ancestry of the sample in hand. The list of
 161 HLA alleles represented in the reference panel is shown in Supplementary File HLAsuppinfo.xlsx

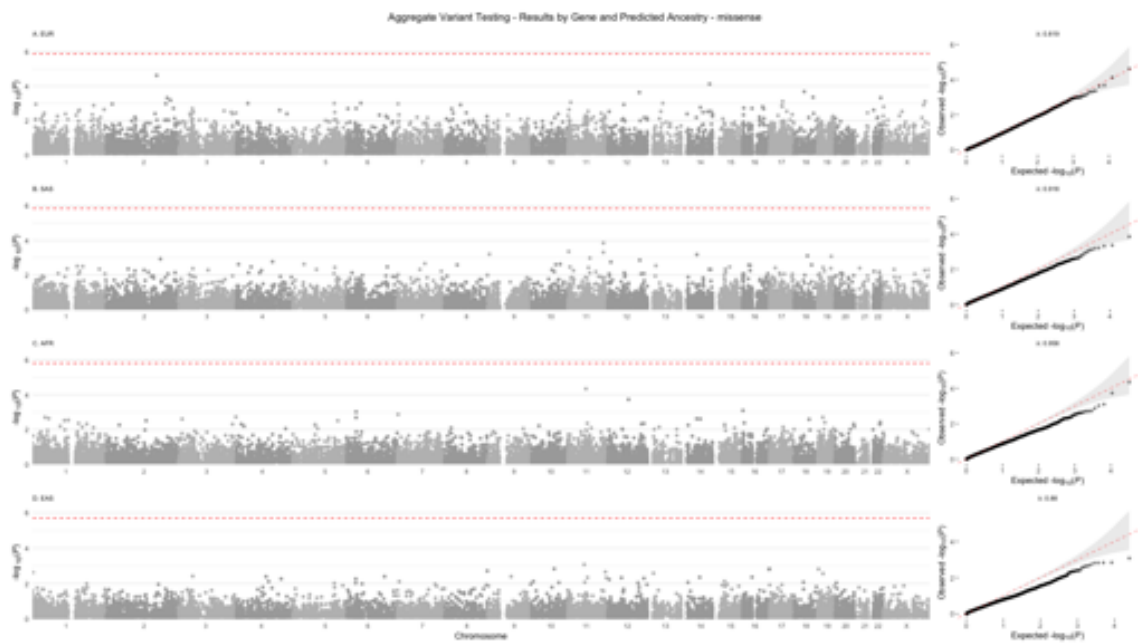

Figure 24: Gene-level manhattan and Q-Q plots per predicted ancestry for the *missense* mask. Each point in the manhattan plot represents a gene. Panels from top to bottom are for EUR (A), SAS (B), AFR (C) and EAS (D). The red dashed lines indicate Bonferonni corrected "gene-wide" P -values (see Table 4).

162 (Sheet A). HIBAG requires genotyped data in PLINK format as input. We lifted over the GRCh38
163 variant calls from aggV2 and aggCOVID_v4.2 for the extended (xMHC) region to hg19, keeping
164 the variants included in the pre-trained classifiers for the seven HLA loci which were present in both
165 the aggV2 and aggCOVID_v4.2 call-sets to ensure that the variants used for the imputation were
166 the same across the two datasets. We applied a threshold of $T=0.5$ on the posterior probabilities
167 returned by HIBAG, as in the original publication.

168 **HLA inference using HLA*LA and concordance between HIBAG and** 169 **HLA*LA callsets**

170 We used a second HLA inference method, HLA*LA⁹, to assess concordance and ensure call rates
171 were comparable between the two methods. HLA*LA (version fe00f82) was used with GRCh38
172 IMGT population reference graphs to infer classical HLA types at G-group resolution for the three
173 class I genes (HLA-A, HLA-C, HLA-B) and four class II genes (HLA-DRB1, HLA-DQA1, HLA-
174 DQB1, HLA-DPB1) that were also imputed with HIBAG. HLA*LA implements a graph alignment
175 model for HLA type inference, based on the projection of linear alignments onto a variation graph.
176 Whole-genome sequencing BAM/CRAM files including unmapped reads were used as input. Where
177 CRAM files were used (alignments from aggCOVID_v4.2 cohort), the reference genome FASTA file
178 used for the original alignment was also provided.

179 Note that at time of writing, only 82% of aggV2 and aggCOVID_v4.2 samples had their HLA
180 types inferred by HLA*LA (Supplementary File HLA suppinfo.xlsx (Sheet B)). All samples had their
181 HLA types imputed using HIBAG.

182 For samples for which we had both HIBAG and HLA*LA calls (n=45,796), we compared the 4-digit
183 resolution alleles called from HIBAG with the alleles called from HLA*LA. As HLA*LA calls alleles
184 at G-group resolution, we took all 4-digit alleles belonging to each G-Group and compared these to
185 the HIBAG calls. For example, if a sample is called as A*01:01:01G, the mapped HLA alleles at
186 4-digit resolution within HLA*LA are 01:01, 01:04, 01:10, 01:13, 01:14, 01:15, 01:22, 01:32, 01:37,
187 01:45, 01:56, 01:81, 01:87. These were compared against the HIBAG 4-digit calls. If the 4-digits
188 matched exactly (in either diploid combination - i.e. 01:01 / 01:04 vs 01:04 / 01:01), then sample
189 alleles were deemed concordant. We found that >96% of calls were identical between HIBAG and
190 HLA*LA.

191 The percentage of concordant calls between HIBAG and HLA*LA by ancestry and locus is shown in
192 Supplementary File HLA suppinfo.xlsx (Sheet C).

193 **HLA Association Tests**

194 HLA calls from HIBAG were aggregated into a single multi-sample VCF file containing sample
195 genotypes for all observed HLA calls. Per sample, the genotypes of any allele call with posterior
196 probability < 0.5 were set to missing. If a sample then had a missing genotype for a particular
197 allele, all other alleles at that locus were also set to missing. For each locus, samples that did not
198 harbour a specific HLA allele (either in a heterozygous or homozygous alternate state), were set to
199 homozygous reference; unless already set to missing from the above mask.

200 HLA association analysis (single variant association tests) was run under an additive model using
201 SAIGE (logistic mixed-model regression) version 0.44.5; in an identical fashion to the SNV GWAS.

202 The multi-sample VCF of aggregated HLA type calls from HIBAG were used as input. The set
203 of 60K high-quality common SNPs `aggCOVID_v4.2_aggV2_HQSNPs` were used to create the
204 GRM and variance ratio files. HLA association tests were run per ancestry (EUR, SAS, EAS, AFR)
205 on unrelated individuals for the `sev_vs_mld_aggV2` cohort. Each HLA association test was run
206 using: *sex*, *age*, *age*², *age* × *sex*, and the first 20 ancestral principle components as covariates. No
207 minimum minor allele count / frequency threshold was set. Results can be seen in Supplementary
208 File `HLAsuppinfo.xlsx` (Sheet D). Note this table combines the results for all ancestries (EUR, SAS,
209 EAS, and AFR) - which is referenced in the first column of the table. The table is sorted by ancestry
210 and alphabetically by allele.

211 HLA-DRB1*:04:01 was the only genome-wide significant HLA allele ($OR = 0.80$, $95\%CI = 0.75 -$
212 0.86 , $P = 1.6 \times 10^{-10}$, in EUR), having a protective effect (casesMAF: 9.6%, controlsMAF: 11.7%).
213 In Europeans, the DRB1*04:01 allele had a low rate of missingness (call rate >0.92 at T=0.5
214 posterior probability threshold), and was in Hardy-Weinberg equilibrium for both cases ($p=0.32$)
215 and controls ($p=0.17$). The observed allele frequency for HLA-DRB1*04:01 was 0.1%, 0.08%, and
216 0.02% for AFR, EAS, and SAS cohorts respectively. A meta-analysis was performed using METAL
217 with an inverse-variance weighted method across the four populations. DRB1*04:01 remained the
218 only significant association ($OR = 0.80$, $95\%CI = 0.75 - 0.86$, $P = 1.4 \times 10^{-10}$), Supplementary File
219 `HLAsuppinfo.xlsx` (Sheet E).

220 Conditional Analysis

221 We conducted a conditional analysis, controlling for the HLA-DRB1*04:01 allele, on the main
222 GWAS results within the extended MHC region. This analysis was performed on the European
223 `sev_vs_mld_aggV2` cohort. To do this, we firstly regressed out the effect of DRB1*04:01 (including
224 *age*, *sex*, *age* × *sex*, *age*², and the first 20 population PCs), and performed linear regression on
225 the residuals using the GWAS variant genotypes as the dependent variable. No variants within
226 the extended MHC remained genome-wide significant upon conditioning on DRB1*04:01. The top
227 GWAS signal (chr6:32623820 T/C; $OR = 0.88$, $95\%CI = 0.84 - 0.92$, $P = 3.3 \times 10^{-9}$) was attenuated
228 following conditional analysis ($P = 0.001$). Figure 25 shows the results of the combined HLA and
229 GWAS association results and the conditional analysis.

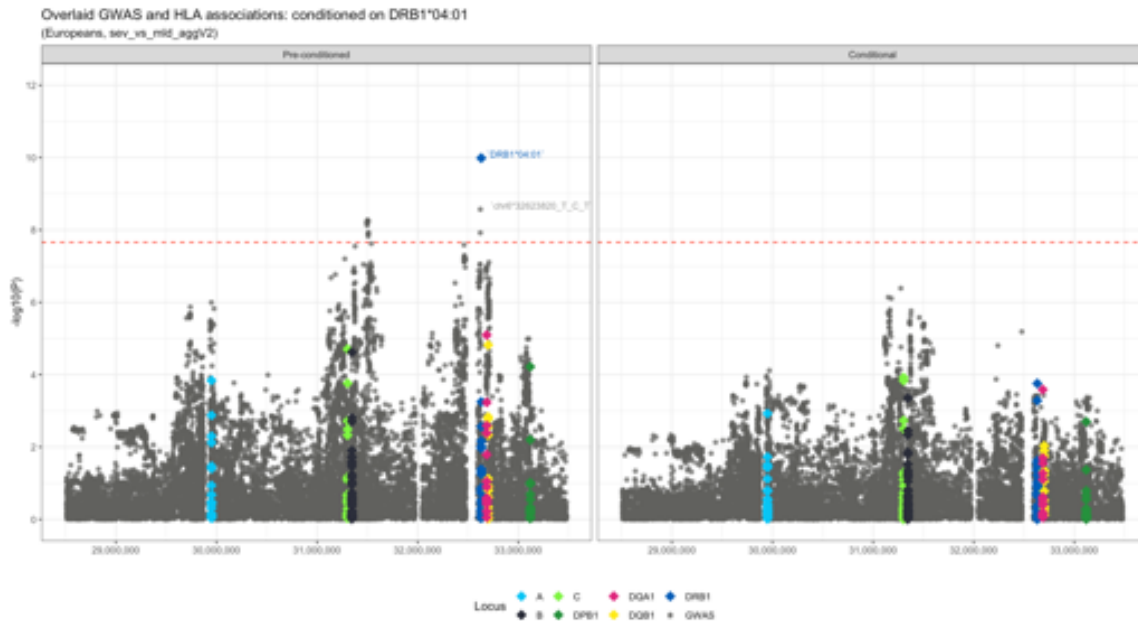

Figure 25: Manhattan plot of HLA and GWAS signal across the extended MHC region for the European sev_vs_mld_aggV2 cohort. Grey circles mark the GWAS (small variant) associations and diamonds represent the HLA each allele association, coloured by locus. The lead variant from the GWAS and lead allele from HLA are labelled. The left-panel shows the raw association $-\log_{10}(p\text{-values})$ per variant - prior to conditional analysis. The right-panel shows the $-\log_{10}(p\text{-values})$ per variant following conditioning on DRB1*04:01. The dashed red line is the genome-wide significance threshold for Europeans.

230 **Meta-analysis by information content (MAIC)**

231 In order to put the results in the context of existing knowledge of host genes implicated in SARS-
 232 CoV-2 replication or pathophysiology of COVID-19, we use meta-analysis by information content
 233 (MAIC)¹⁰ to incorporate lists of named genes from a large systematic review of in vitro and in vivo
 234 studies.¹¹ Remarkably, the top 2000 named genes in our metaTAS contributes 19.5% of the total
 235 information content in this composite analysis (Supplementary Figure 26). Full results are available
 236 at baillielab.net/maic/covid.

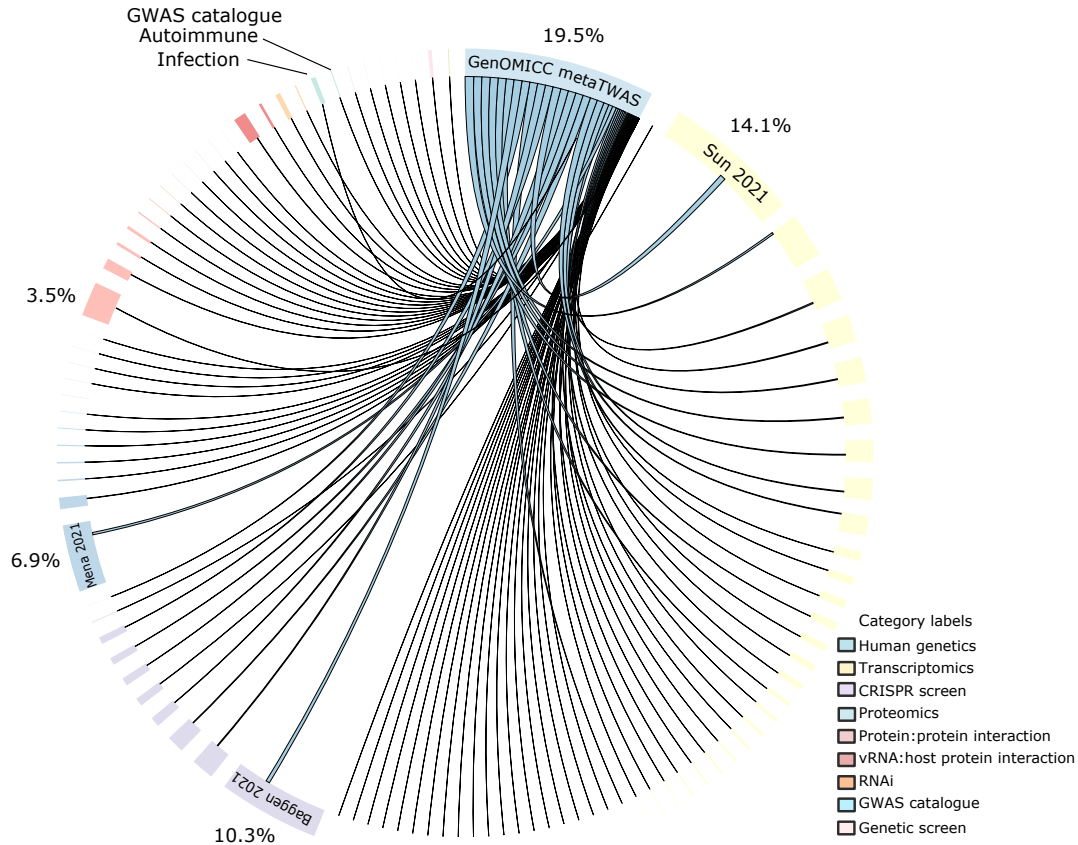

Figure 26: Circular diagram of shared information content among data sources using MAIC analysis. Each data source is represented by a coloured block on the outer ring of the circle; the size of data source blocks is proportional to the summed information content of the input list—that is, the total contribution that this data source makes to the aggregate, calculated as the sum of the MAIC gene scores contributed by that list and represented numerically for datasets with the highest information content. Lines are coloured according to the dominant data source. Data sources within the same category share the same colour (legend). The largest categories and data sources are labelled. An interactive version of this figure is available at baillielab.net/maic/covid.
