27 **Abstract:**

28 The mechanisms explaining progression to severe COVID-19 remain poorly understood. It has
29 been proposed that immune system dysregulation/over-stimulation may be implicated, but it is not clear
30 how such processes would lead to respiratory failure. We performed comprehensive multiparameter
31 immune monitoring in a tightly controlled cohort of 128 COVID-19 patients, and used the ratio of oxygen
32 saturation to fraction of inspired oxygen (SpO_2 / FiO_2) as a physiologic measure of disease severity.
33 Machine learning algorithms integrating 139 parameters identified IL-6 and CCL2 as two factors predictive
34 of severe disease, consistent with the therapeutic benefit observed with anti-IL6-R antibody treatment.
35 However, transcripts encoding these cytokines were not detected among circulating immune cells. Rather,
36 in situ analysis of lung specimens using RNAscope and immunofluorescent staining revealed that elevated
37 IL-6 and CCL2 were dominantly produced by infected lung type II pneumocytes. Severe disease was not
38 associated with higher viral load, deficient antibody responses, or dysfunctional T cell responses. These
39 results refine our understanding of severe COVID-19 pathophysiology, indicating that aberrant cytokine
40 production by infected lung epithelial cells is a major driver of immunopathology. We propose that these
41 factors cause local immune regulation towards the benefit of the virus.

42 Introduction

43 The clinical manifestations of COVID-19 range in severity from asymptomatic infection to critical
44 illness and death, yet the mechanisms by which SARS-CoV-2 cause morbidity and mortality have yet to be
45 fully elucidated. It has been proposed that an excessive immune response may cause immunopathology in
46 affected target organs, particularly the lower respiratory tract. Several large studies of hospitalized patients
47 demonstrated that disease severity and mortality are correlated with elevated levels of inflammatory
48 cytokines, suggesting a potentially dysregulated immune response to infection¹⁻⁴. Consistent with this
49 notion, the steroid dexamethasone improved outcomes in severe and critically ill patients^{5,6}. IL-6 specifically
50 has been proposed as a functionally important cytokine,⁷ and the anti-IL-6R antibody (Ab) tocilizumab
51 provided a survival benefit in critically ill COVID-19 patients^{8,9}.

52 SARS-CoV-2-infected patients can develop both T cell and B cell responses^{2,3,10-12}. Some groups
53 of patients appear to develop phenotypically distinct immune responses, which have been hypothesized to
54 be maladaptive^{2-4,10,13}. This includes skewing towards a Th2 or Th17 phenotype² or uncoordinated B and/or
55 T cell responses¹⁰. However, these studies used heterogeneous cohorts of patients at different phases of
56 infection, and concurrent disease states or immunosuppression may complicate the interpretation of
57 immunologic studies. African American and Latino patients are disproportionately affected by the SARS-
58 CoV-2 pandemic, but they generally are under-represented in translational research studies. Similarly,
59 analysis of non-hospitalized patients with mild COVID-19 has been limited. Based on these considerations,
60 we examined the longitudinal immune response from non-immunosuppressed, predominantly African
61 American and Latino patients. We defined disease severity based on the ratio of oxygen saturation to
62 fraction of inspired oxygen (SpO₂ / FiO₂). Immune parameters associated with disease severity were
63 identified based on an unbiased machine learning algorithm. When a disconnect was identified between
64 elevated serum cytokine levels yet lack of evidence for their production by immune cells, lung tissue was
65 studied for in situ expression of key immune genes.

66 **Results**

67 **Patients and definition of disease severity**

68 We analyzed 101 hospitalized COVID-19 patients, 27 non-hospitalized COVID-19 outpatients, and
69 22 healthy donors (HD) as part of a COVID-19 biobanking protocol (Fig 1a). Sixty-seven additional COVID-
70 19 patients were excluded from analysis because of potential immunological confounders, as listed in
71 Supplementary Table 1. Samples from patients who received the anti-IL-6R antibody tocilizumab were
72 excluded from cytokine analyses, as tocilizumab can modulate levels of IL-6 and other cytokines¹⁴.
73 Demographic characteristics of the study cohort are shown in Supplementary Table 2. Our patient
74 population was 68% African-American with a median age of 55 years. To avoid over-sampling bias from
75 severe patients who had more timepoints available for analysis, we used the maximum level of soluble
76 factors quantified per patient from an early (Day 1-9) and late (Day 10-30) timepoint post-symptom onset,
77 except when assessing cytokine kinetics.

78 To obtain an objective measure of disease severity to correlate with immunologic parameters, the
79 pulse oximeter oxygen saturation (SpO₂) / fraction of inspired oxygen (FiO₂) ratio (S/F ratio) was calculated
80 for each patient over time (Fig 1a). The S/F ratio is analogous to the PaO₂/FiO₂ (P/F) ratio used in ARDS
81 studies^{15,16} and has been validated as an independent correlate of severity in SARS-CoV-2 infection¹⁶.
82 Patients were divided into three groups - mild, moderate, and severe - on the basis of their worst daily mean
83 S/F ratio during their initial hospitalization. Patients with normal oxygen saturation on room air and
84 outpatients were defined as mild (S/F > 315), while the majority of inpatients on non-invasive or invasive
85 ventilatory support were classified as severe (Supplementary Fig 1a). The S/F ratio is a dynamic and
86 objective measurement of a patient's respiratory status over the course of illness and hospitalization
87 (Supplementary Fig 1c) and provides a continuous scale of disease severity.

88

89 **Robust adaptive immune responses in infected patients**

90 Consistent with other studies¹⁷, severe patients had higher maximum C-reactive protein (CRP),
91 ferritin, and D-dimer levels compared to mild patients (Supplementary Fig 1d). The absolute lymphocyte
92 count decreased with worsened disease severity, and many patients were lymphopenic.

93 One hypothesis potentially explaining disease severity was a diminished or delayed adaptive
94 immune response, leading to failed viral clearance. We therefore measured total immunoglobulin (Ig), IgG,
95 and IgM antibody titers against the SARS-CoV-2 Spike glycoprotein and its Receptor Binding Domain
96 (RBD). RBD binds to angiotensin-converting enzyme 2 (ACE2) receptor on human cells and is the primary
97 target for neutralizing antibodies^{18–20}. By day 10 post-symptom onset, 44 of 45 evaluable patients had
98 detectable anti-Spike and anti-RBD total Ig (Figure 1b). IgG titers to Spike and RBD persisted through the
99 acute phase of infection (day 10-19), recovery (day 20-59), and into late recovery (day 60 – 120), whereas
100 IgM titers started to decline in the recovery phase, as expected (Figure 1c). There was a corresponding
101 increase in the frequency of antibody-producing plasmablasts, class switched IgD^{neg} B cells, and T follicular
102 helper cells (Tfh) by day 9 (Fig 1d). When examining Ab responses by disease severity, patients with
103 severe disease developed comparable maximum anti-RBD and anti-Spike antibody titers compared to
104 patients with mild or moderate disease (Figure 1b, 1e), indicating that a failed Ab response was not causal
105 for progression to severe disease. Spike and RBD titers also did not correlate with age (Supplementary Fig
106 2a) or gender (Supplementary Fig 2b). IL-6 is known to be involved in plasma cell differentiation and
107 antibody production^{21,22}, so we investigated whether treatment with the IL-6R antagonist tocilizumab
108 affected SARS-CoV-2 antibody generation; yet no differences were observed (Supplementary Fig 2c). Anti-
109 viral medications such as remdesivir could have decreased antigen load and led to a lesser Ab response;
110 however, no diminution of Ab response was observed (Supplementary Fig 2c). Consistent with these
111 results, nasopharyngeal viral load as measured by digital droplet PCR (ddPCR) did not differ between
112 patients with mild, moderate, or severe disease (Supplementary Fig 2d).

113 Analysis of circulating T cells by flow cytometry (Supplementary Fig 3) revealed a decrease in
114 the percentage of CD8⁺ T cells relative to total CD45⁺ cells in severe patients (Fig 2a). The percentages of
115 CD8⁺ central memory (CM) and effector memory (EM) cells decreased at both early and late time points,
116 while the frequency of terminally differentiated memory (TEMRA) cells was relatively stable (Fig 2a). The
117 percentage of CD4⁺ CM cells increased in patients while the percentage of CD4⁺ EM cells remained
118 unchanged. The percentage of T helper type 1 (Th1) cells was increased in severe COVID-19 patients
119 while the percentage of T helper type 2 (Th2) cells did not change. CD4⁺ T cells upregulated CD57, a

120 marker of cytotoxic terminally differentiated cells,^{23,24} and CD8⁺ T cells upregulated CD95 (Supplementary
121 Fig 4a,4b).

122 CD38 and HLA-DR are markers of activated T cells during viral infections²⁵, and this population
123 was increased among both CD4⁺ and CD8⁺ T cells in COVID-19 patients of all disease severities (Fig 2b).
124 It was particularly striking in CD8⁺ T cells, where 42% (21 / 50) of patients had > 5% of all CD8⁺ T cells
125 expressing these activation markers between days 10-30. Thus, despite a relative overall lymphopenia,
126 there was an abundance of activated T cells in severe patients. Self-clustering analysis using UMAP and
127 FlowSOM algorithms²⁶ showed COVID-19 patients had increased percentages of activated CD8⁺ (cluster
128 4) and CD4⁺ (cluster 11) cells expressing high levels of CD38, HLA-DR, and CD95 (Supplementary Fig 4c-
129 e). CD8⁺ CM cells and multiple subsets of CD4⁺ T cells upregulated CD28 (Supplementary Fig 4a,4b).
130 There were no significant differences in the percentages of CD4⁺ or CD8⁺ T cells expressing PD-1, although
131 modest upregulation of PD-1 was seen on CD4⁺ EM and CD8⁺ EM and TEMRA cells (Fig 2c,
132 Supplementary Fig 4a,b). There was an increased percentage of CD8⁺ T cells expressing TIM-3 (Fig 2c).
133 The proportion of regulatory T cells (Tregs) also increased in COVID-19 patients (Fig 2a), suggesting a
134 counter-regulatory mechanism in response to increasing levels of T cell activation.

135 Several studies have shown that inhibitory receptors including PD-1 are upregulated on SARS-
136 CoV-2 specific T cells, and have suggested that PD-1^{high} cells in COVID-19 infection are exhausted^{17,27-29}
137 or have decreased polyfunctionality^{28,30}. However, PD-1 can also be upregulated in acutely activated T
138 cells^{3,31}. To determine whether there were differences in IFN- γ production by SARS-CoV-2-specific T cells,
139 we used an ELISPOT to measure IFN- γ production after stimulation with overlapping HLA class I & II 15-
140 mer peptides from the S, M, and N proteins of SARS-CoV-2. IFN- γ production was seen as early as day 8
141 after symptom onset, and the degree of IFN- γ production was similar between patients with different
142 disease severities (Supplementary Fig 4f).

143 To determine if PD-1 on these cells represents a marker of activation or exhaustion, we used
144 intracellular cytokine staining to measure polyfunctionality after S/M/N peptide stimulation. Compared to
145 mild patients, severe patients had higher percentages of polyfunctional CD4⁺ T cells producing IFN- γ , TNF-
146 α , and/or IL-2 in response to S/M/N peptide stimulation (Fig 2d-f). Furthermore, cytokine production was
147 concentrated in the PD-1⁺CD4⁺ T cells, indicating that PD-1 represents an activation marker rather than a

148 marker of dysfunction in this context. There was a similar trend with PD-1⁺ CD8⁺ T cells in severe patients,
149 but this was not significant due to increased patient-to-patient variability in the CD8⁺ T cell response
150 (Supplementary Fig 4g). Cytokine-producing T cells were enriched amongst the CD38⁺HLA-DR⁺ population
151 (Fig 2d,2f), consistent with this population containing virus-activated T cells. We conclude that the adaptive
152 immune response is robust in severe COVID-19 patients and that lack of virus-specific immunity is not
153 contributory to the progression to disease severity.

154 Patients with SARS-CoV-2 also had a serum cytokine and chemokine profile consistent with
155 increased T cell activation. Levels of CCL19 and CCL20, which recruit T cells to lymph nodes for activation,
156 increased with disease severity (Fig 2g). Severe patients had higher levels of sCD25/IL-2Ra, which is
157 cleaved and released upon T cell activation. CCL5 and CXCL10 recruit T cells to sites of inflammation,
158 and were elevated in the serum of COVID-19 patients. CXCL10 also increased with disease severity.
159 Levels of CCL19, CCL20, and CD25/IL-2Ra remained elevated over time in severe patients, while CCL5
160 and CXCL10 levels declined over time in both mild and severe patients (Fig 2h). Patients with severe
161 disease had increased levels of T cell survival cytokines IL-15 and IL-7 (Supplementary Fig 4h). Levels of
162 the immunoregulatory molecules IL-10 and IL-1RA were increased in patients with SARS-CoV-2,
163 suggestive of an expected negative feedback loop in response to increasing T cell activation^{32,33}.

164

165 **Innate immune cells and circulating cytokines**

166 Analysis of the innate immune response demonstrated a decreased proportion of circulating NK
167 cells and particularly the CD16⁻ NK cell subset at early and late timepoints (Fig 3a). Frequencies of dendritic
168 cell (DC) subsets remained mostly unchanged other than a decrease in CD123⁺ plasmacytoid dendritic
169 cells at late timepoints (Supplementary Fig 5a). However, the level of CD86 increased in plasmacytoid DCs,
170 indicating a more activated status. CD1c⁺ DCs also had higher levels of Tim-3 at late time points after
171 SARS-CoV-2 infection. The proportions of neutrophils, non-classical monocytes, and intermediate
172 monocytes were increased in patients with COVID-19 compared to healthy controls (Fig 3a). While the
173 percentage of classical monocytes was unchanged, the mean fluorescence intensity (MFI) of CD86 and
174 HLA-DR was decreased in infected patients (Fig 3a), suggesting the emergence of less-mature monocytes
175 from the bone marrow. This is further supported by increased levels of the myeloid growth factor GM-CSF

176 in the serum of patients with SARS-CoV-2 infection (Fig 3b), and a negative correlation between GM-CSF
177 and HLA-DR levels on intermediate monocytes ($R^2 = 0.15$, $p = 0.004$) (Supplementary Fig 5c). These
178 parameters are consistent with tissue repair-type macrophages being favored during SARS-CoV-2
179 infection.

180 Patients with SARS-CoV-2 had increased levels of cytokines responsible for recruiting neutrophils,
181 monocytes and macrophages to sites of inflammation, including the neutrophil chemoattractants IL-8,
182 CXCL1, CXCL2, and the monocyte chemoattractants CCL2, CCL4, and CX3CL1 (Fig 3b). IL-8, CCL2, and
183 CX3CL1 also increased with disease severity. Distinct groups of cytokines clustered together in correlation
184 plots at late time points (Fig 3c), particularly in severe patients. CCL2 levels remained high over time in
185 severe patients, and higher levels of CCL2 also correlated with a longer duration of moderate or severe
186 illness ($R^2 = 0.17$, $p = 0.00737$) (Fig 3d-e).

187 IL-6 has been identified as a pathologic mediator of cytokine release syndrome after CAR-T cell
188 treatment, and it has been hypothesized that a similar phenomenon may be driving severe pathology in
189 some COVID-19 patients⁷. IL-6 signals through the IL-6R and gp130 complex. Gp130 is ubiquitously
190 expressed, while IL-6R expression is normally limited to immune cells and hepatocytes. IL-6 can also form
191 a complex with soluble IL-6R (sIL-6R α) and signal in trans through gp130 in cells that do not express the
192 IL-6R. We found that IL-6 levels increased with disease severity, while sIL-6R α and gp130 levels were
193 similar between severity groups (Fig 3b). While there was a correlation between CRP and IL-6 levels, there
194 were many patients who had a high CRP but only a modest increase in IL-6 (Supplementary Fig 5d). Levels
195 of IL-6 remained high at late timepoints in severe patients when compared to mild (Fig 3d), and levels of
196 soluble gp130 were lower in severe patients at late timepoints (Supplementary Fig 5e). sIL-6R α levels
197 remained high over time in both mild and severe patients. Interestingly, the duration of moderate or severe
198 disease positively correlated with IL-6 levels and negatively correlated with soluble levels of gp130, which
199 is an endogenous inhibitor of IL-6 trans-signaling³⁴⁻³⁷ (Fig 3e, Supplementary Fig 5f).

200 In order to better understand the pathophysiology that differentiates severe patients from mild or
201 moderate patients, we used the Random Forest machine learning algorithm with 3-fold cross-validation to
202 model the impact of 139 defined immune parameters in an unbiased fashion. From the resulting model, the
203 highest importance features were extracted (Figure 3f), and linear regression modeling was used to

204 determine the relative impact of each feature. At early time points (D1-9), severe patients showed evidence
205 for an active innate immune response (elevated G-CSF, IL-8, and the percentage of neutrophils) as well as
206 an activated T cell response (elevated CXCL10, IL-7, and IL-15). Integrating the data from all phases (D1-
207 30) of the immune response, a signature suggestive of T cell recruitment and activation with elevated
208 CCL20, CXCL10, and sCD25/IL-2R was evident in severe patients, consistent with the notion that
209 persistence of virus drives a continued T cell response. Additionally, severe patients had elevated levels of
210 the macrophage related factors CCL2 and IL-6, with elevated CCL2 being the overall top-ranked
211 immunological predictor of severe disease.

212

213 **IL-6 and CCL2 are produced by infected lung epithelial cells**

214 Elevated levels of serum IL-6 and CCL2 were each associated with and predictive of severe
215 COVID-19 disease. CCL2 is known to recruit macrophages, particularly M2 macrophages, into tissues. A
216 detrimental role for IL-6 has been supported by studies showing improved clinical outcome upon treatment
217 with the anti-IL-6R antibody tocilizumab⁹. Based on prior work studying cytokine-release syndrome in CAR-
218 T cell therapy^{38,39} and IL-6 production in infectious models⁴⁰⁻⁴², it has been assumed that IL-6 in COVID-19
219 patients is being produced by macrophages⁴³. However, in our cohort examining representative patients
220 having “high” versus “low” serum IL-6 levels at the protein level (Supplementary Fig 6a), no difference in
221 mRNA for either IL-6 or CCL2 was observed among peripheral level blood mononuclear cells
222 (Supplementary Fig 6c-d). This result is consistent with the flow cytometric analysis of circulating
223 monocytes, which indicated an immature and possibly tissue repair phenotype rather than an inflammatory
224 one (Fig 3a). Together, these results suggested that the source of these cytokines might not be immune
225 cells, but rather raised the possibility that virus-infected cells in the lung might be the major source. We
226 therefore examined expression of IL-6 and CCL2 mRNA in lung tissue from a cohort of 10 fatal COVID-19
227 cases listed in Supplementary Table 3. We performed a multispectral immunofluorescence assay
228 combining RNA *in situ* hybridization (RNA-ISH) for SARS-CoV-2 RNA and IL-6 or CCL2 mRNA, along with
229 protein immunofluorescence (IF) staining to identify the cells of origin. Thyroid transcription factor 1 (TTF1)
230 was used to identify type 2 pneumocytes, and CD45 was utilized to identify leukocytes (Fig 4a,
231 Supplementary Fig 7a). SARS-CoV-2 RNA was detected in all of the autopsy lung specimens.

232 Unexpectedly, the vast majority of IL-6 transcripts were detected in cells that did not co-stain for the
233 macrophage markers CD68 or the M2 macrophage marker CD163 (Supplementary Fig 6e-f). Interestingly,
234 large numbers of TTF1⁺ type 2 pneumocytes expressed IL-6 mRNA, with a high percentage of these cells
235 also positive for SARS-CoV-2 RNA (Fig 4a-c). Quantitative analysis showed TTF1⁺ type 2 pneumocytes
236 were the predominant IL-6-expressing cell type, greatly outnumbering CD45⁺ immune cells (Fig 4b,c).
237 Among the IL-6 positive populations, type 2 pneumocytes relative to CD45⁺ cells showed greater IL-6
238 expression on a per cell basis, as indicated by a greater number of TTF1⁺ cells with higher mean staining
239 intensity for IL-6 (Fig 4d). Similarly, CCL2 expression was particularly abundant on TTF2⁺ type 2
240 pneumocytes (Supplementary Fig 7a-d). Together these data show that virus-infected lung epithelial cells
241 are the major source of IL-6 and CCL2 in SARS-CoV-2 infected lungs.

242

243 **Discussion**

244 Here we show that IL-6 and CCL2 are major factors that discriminate severe infection from mild or
245 moderate disease. IL-6 is known to be produced by innate immune cells such as macrophages or dendritic
246 cells, and by non-immune cells such as epithelial cells or fibroblasts. In allergic asthma^{44,45}, SARS-CoV-
247 ¹⁴⁰, influenza⁴¹, and pneumovirus infection models⁴², IL-6 has been shown to be produced by macrophages
248 and other myeloid cells, whereas IL-6 can be produced by cultured nasal epithelial cells infected with
249 RSV^{46,47}. In mouse models of CAR-T cell cytokine release syndrome, macrophages and monocytes are
250 the predominant source of IL-6^{38,39}, while vascular endothelial cells have also been shown to produce IL-6
251 in CRS autopsy specimens⁴⁸. Our results from human autopsy specimens unexpectedly show that the
252 predominant source of IL-6 and CCL2 *in vivo* during SARS-CoV-2 infection is from infected epithelial cells.
253 Our data are consistent with scRNA-seq studies of PBMCs from COVID-19 patients that showed a
254 discrepancy between serum cytokine measurements and the cytokine transcripts of CCL2 and IL-6 among
255 PBMCs⁴⁹⁻⁵³. Large numbers of epithelial pneumocytes co-stained with IL-6 or CCL2 and SARS-CoV-2 RNA
256 probes, implicating direct cytokine induction by the virus. When considering potential mechanisms of
257 cytokine production, it has been demonstrated that SARS-CoV-2 induces Nuclear Factor kappa B (NF-κB)
258 upregulation and IL-6 production in cultured lung alveolar and epithelial cells^{54,55}. CCL2 and other
259 inflammatory mediators are also induced via the NF-κB pathway⁵⁶.

260 In mouse models of coronavirus infections, sustained CCL2 expression enhanced the lethality of
261 disease, and promoted immunopathology with a destructive monocyte/macrophage response and
262 ineffective virus clearance⁵⁷. The effect of excess CCL2 in human SARS-CoV-2 has not yet been
263 elucidated. CCL2 may recruit wound-healing M2 macrophages, which can facilitate lung tissue repair by
264 stimulating type 2 pneumocyte expansion⁵⁸, thereby triggering a process capable of enhancing virus
265 propagation⁵⁹. The anti-IL-6R antibody tocilizumab improves survival in critically ill patients⁹, implying that
266 excessive IL-6 is detrimental to the host. Elevated levels of IL-6 in cancer models have been mechanistically
267 linked to decreased DC survival and activation, and consequently impaired CD8⁺ T cell priming⁶⁰. As such,
268 elevated IL-6 expression in the lung during SARS-CoV-2 infection might impair DC function within the
269 infected lung. Thus, we speculate excess IL-6 and CCL2 may favor the virus by promoting a local defect in
270 DC priming of T cells and impaired reactivation of virus-specific T cells locally within the lung and/or by
271 supporting the survival and expansion of infected lung epithelial cells via recruitment of M2 wound-healing
272 macrophages.

273 Corticosteroids, which improve survival for COVID-19 patients requiring supplemental oxygen⁵,
274 exert their anti-inflammatory effects through NF- κ B inhibition and other pathways⁶¹. It has been assumed
275 that steroids are acting on immune cells, but they could also be inhibiting NF- κ B in infected epithelial cells
276 or other host cells. Together, these observations suggest a model whereby SARS-CoV-2 induces NF- κ B,
277 leading to an increase in IL-6 and CCL2 production in type 2 pneumocytes, creating favorable conditions
278 for viral persistence, alveolar damage, and ultimately respiratory failure. Additional studies are needed to
279 determine the impact of lung-derived IL-6 and CCL2 on immune clearance of SARS-CoV-2.

280 Robust adaptive immune responses were seen in patients with mild and moderate disease and
281 were even higher in patients with severe disease, arguing that the lack of a protective immune response
282 did not cause severe disease. CD38⁺HLA-DR⁺ CD4⁺ and CD8⁺ T cells were polyfunctional, and patients
283 with a higher disease severity had more cytokine producing CD4⁺ T cells. These cytokines were being
284 produced by PD-1⁺ cells, indicating that PD-1 in this context is a marker of activation, not exhaustion. This
285 is consistent with other recent work showing that tetramer⁺ PD-1⁺, SARS-CoV-2-specific CD8⁺ T cells
286 produce cytokines⁶². In patients with severe disease, markers of T cell activation such as sCD25/IL-2R
287 remain high at late time points, suggesting an ongoing immune response against the virus. In some severe

288 patients who ultimately die from SARS-CoV-2, persistent viral RNA has been demonstrated in longitudinal
289 saliva samples from the Iwasaki group⁶³, as well as in our autopsy lung samples. Increased antigen load
290 and duration of antigenic exposure leads to increased T and B cell expansion and differentiation in other
291 experimental models⁶⁴. While we cannot rule out that the increased adaptive immune response causes
292 immunopathology, the increase in regulatory modulators such as IL-10 and Tregs suggests that the immune
293 system is appropriately executing negative feedback pathways. Our data suggests that the immune
294 response to SARS-CoV-2 is a functional and proportional response to infection, and infected pneumocytes
295 are the major source of IL-6 and CCL2, thus revising the paradigm of how we understand the pathogenesis
296 of severe SARS-CoV-2 infection.

297 **Supplementary Table 1: Patients excluded from immune analysis**

Reasons for exclusion of patients from immune analyses:
Trauma/surgery during admission for SARS-CoV-2
Systemic bacterial infection or bacteremia (or high clinical suspicion thereof)
Active malignancy
Biologic / Immune Suppressant use within the last 30 days \geq 7.5 mg of prednisone (or within last 6 months for long-acting monoclonal antibodies). Samples prior to receipt of steroids were eligible for inclusion.
Chemotherapy or Immunotherapy within the last 6 months
Sickle Cell Disease with crisis within the last 30 days
Solid organ transplant
Concurrent pneumothorax
Saddle pulmonary embolism with hemodynamic compromise
Cardiogenic shock in a patient with end stage heart failure; out of hospital cardiac arrest
Delivered of a pregnancy during admission for SARS-CoV-2

298

299 **Supplementary Table 2: Demographic characteristics of patient cohorts**

	Healthy donor	Mild	Moderate	Severe	Total SARS-CoV-2 positive cohort	p-value (mild vs severe)
Number of Patients	22	69	30	29	128

308 **Acknowledgements**

309

310 We would like to thank Marcellus Johnson, Melanie Veron, and Lauren Wall for clinical research support,
311 Hongyuan Jiao, PhD, Glee Guilan Li, and Shuhan Yu, MD for biobank sample processing, as well as
312 Rajlakshmi Krishnamurthy MD and Geneatra Green for operational support. Thanks to Laura Johnson from
313 the flow cytometry core, Melvin Lye from Curiox, and Chris Fleming from Cytex for assistance with assay
314 design. The HIM and flow cytometry cores are supported by the University of Chicago Cancer Center
315 Support Grant P30CA014599, and the Center for Research Informatics and Redcap are supported by the
316 UL1TR000430 from NCATS/NIH. SJR, JY and CSC are supported by the T32 CA009566. JAT is
317 supported by 5K12CA139160-09 from NIH. RR was funded by the German Research Foundation (DFG RE
318 4468/1-1). MLM received funding from NIAID Collaborative Influenza Vaccine Innovation Centers (CIVIC)
319 contract 75N93019C00051. YL and LSC are supported by R01GM108711.

320

321 Author Contributions:

322 SJR, JAT, ARP, TFG conceived and designed the study. SJR, JAT, ARP, AP, LK, GWS, CSC, MK, SS,
323 and MLM consented and recruited patients. YZ processed and stored patient samples and isolated RNA.
324 SJR, JAT, ARP, JF, KC performed flow cytometric assays; AC and JCB performed ELISAs; AC, JAT, BAF,
325 YZ performed cytokine assays; JAT, KH, RR performed microscopy, MFA and SO performed ddPCR.
326 YSJR, JAT, ARP, JY, JF, AC, EFH, KC, YL, JCB, MFA, SO and BAF analyzed data. JY, EFH, YL, and BAF
327 performed bioinformatic analysis, did statistics, and graphed data. ML, KB, K-TJY, JM provided materials
328 and samples. RS, ST, EI, JS, LC, TFG provided personnel, supervision, and insights. SJR, JAT, ARP,
329 and TFG drafted the manuscript; all authors helped to edit the manuscript.

330

331 Correspondence and requests for material or data should be directed to TFG.

507 **Methods:**

508 *Patients, sample collection*

509 The COVID-19 biobank study was approved by the University of Chicago Institutional Review
510 Board (IRB 20-0520), and all procedures were performed in accordance with the ethical standards set forth
511 in the 1964 Helsinki Declaration. Informed consent was obtained using paper consent, or a Redcap
512 electronic consent form (when possible) to minimize risk of infection. Patients could choose to donate fresh
513 research blood samples and/or allow leftover material from clinical testing (BMP and nasopharyngeal
514 swabs) to be used for research. Research samples were used for flow cytometry, ELISPOTs, and luminex
515 analysis; ELISAs used both research plasma samples and leftover serum from clinical BMPs. Viral load
516 was measured on leftover viral transport media from clinical nasopharyngeal swabs. Blood was collected
517 from inpatients every 24-72 hours during the first week of their hospitalization, and 1-2 times a week for the
518 remainder of their hospitalization. Blood was collected up to once a week from outpatients during regularly
519 scheduled appointments. Serum from 5 healthy donors was purchased from Cellular Technology Limited;
520 the remainder of the healthy donor samples were obtained from the COVID-19 biobank.

521 For serum, fresh blood was collected into a preservative-free vacutainer tube and allowed to clot
522 for at least 30 minutes at room temperature. Leftover plasma samples collected in heparinized tubes were
523 also obtained from the clinical chemistry lab. Tubes were centrifuged for 20 minutes at 1300 x g at room
524 temperature, and the yellow serum/plasma layers were collected and stored at -80 degC until analysis.

525 For PBMCs, fresh blood was collected into heparinized vacutainer tubes and separated using
526 LeucoSep (Greiner Bio-One) tubes. Cells were washed twice with PBS, counted and resuspended in

527 freezing media containing 90% FBS and 10% DMSO at $5 - 20 \times 10^6$ /mL. Cells were frozen in liquid nitrogen
528 until further analysis.

529

530 *Timepoints used*

531 For analyses divided into early (D0-9) and late (D10-30) phases, the maximal cytokine
532 measurement per patient and the mean of any available flow cytometry measurements per patient in each
533 time period were used. For kinetic analysis of cytokines or antibodies versus DPSO, all available
534 measurements between D1-30 per patient were used. For cytokines versus total non-mild days, the
535 maximal cytokine value between D1-30 was used. Total non-mild days was calculated as the number of
536 hospitalized days with an average S/F ratio of < 315 . For maximal antibody titers, the highest antibody titer
537 measurement between D10-30 per patient were used. Maximum viral load per patient was used. ICS
538 samples were from D11-17 DPSO.

539

540 *Cytokine measurements by Luminex*

541 Human XL Cytokine Luminex Performance Panel Premixed Kit (CCL2/JE/MCP-1, CCL3/MIP-1
542 alpha, CCL4/MIP-1 beta, CCL5/RANTES, CCL19/MIP-3 beta, CCL20/MIP-3 alpha, CX3CL1/Fractalkine,
543 CXCL1/GRO alpha/KC/CINC-1, CXCL2/GRO beta/MIP-2/CINC-3, CXCL10/IP-10/CRG-2, EGF, G-CSF,
544 GM-CSF, Granzyme B, IFN-alpha, IFN-gamma, IL-1 alpha/IL-1F1, IL-1 beta/IL-1F2, IL-1ra/IL-1F3, IL-2, IL-
545 6, IL-7, IL-10, IL-13, IL-15, IL-33, TGF-alpha, TNF-alpha, TRAIL/TNFSF10, VEGF) and human 6plex
546 luminex multiple kits (angiopoietin-2, CD25/IL-2R alpha, gp130, IL-6R alpha, VEGF-c) were purchased from
547 Bio-Techne, and performed according to manufacturer's instructions. Samples were run in duplicate. Any
548 analytes with a bead count < 32 or CV $> 20\%$ between the duplicates was considered to fail QC for that
549 patient and excluded from further analysis.

550

551 *Anti-SARS-CoV-2 antibody ELISA*

552 The SARS-CoV-2 full-length Spike and Receptor Binding Domain (RBD) protein expression
553 constructs were obtained from Florian Krammer and Patrick Wilson⁶⁵, and used to generate recombinant
554 protein for an enzyme-linked immunosorbent assay (ELISA) adapted from established protocols⁶⁶.

555 Recombinant proteins were produced using a Chinese hamster ovary (CHO) cell line expression system
556 and purified using metal-chelate affinity chromatography. Protein integrity was confirmed via SDS-PAGE
557 gel. Overnight, 96-well ELISA plates (Nunc MaxiSorp high protein-binding capacity plate; ThermoFisher)
558 were coated at 4°C with 2 mg/mL of Spike or RBD protein suspended in Phosphate Buffered Saline (PBS)
559 pH 7.4. Plates were blocked with 3% milk powder in PBS containing 0.1% Tween-20 for 1 hour at room
560 temperature. Serum and plasma samples were heated at 56°C for 30 minutes to inactivate virus prior to
561 use. Serial 1:3 dilutions of the samples were prepared in 1% milk in 0.1% PBS-Tween 20, and incubated
562 in duplicate with the blocked plate for 2 hours at room temperature. After 3 washes in 0.05% PBS-Tween
563 20, an HRP-conjugated secondary antibody specific for either total Ig (goat anti-human immunoglobulin Ig,
564 SouthernBiotech), IgM (anti-human IgM, μ -chain specific, Millipore Sigma), or IgG (Goat anti-human IgG
565 (H+L), Jackson ImmunoResearch) were diluted in 1% milk in 0.1% PBS-Tween-20, and added at 1:8000
566 for 1 hour at room temperature. Plates were washed 3 times with 0.1% PBS-Tween 20 before being
567 developed with 3, 3', 5, 5'-tetramethylbenzidine (TMB) substrate kit (ThermoFisher) at room temperature.
568 The reaction was stopped after 15 minutes with 2M sulfuric acid. The optical density (OD) was read at 450
569 nm using a Synergy H4 plate reader (BioTek). The OD values for each sample were background subtracted.
570 A positive control standard was prepared from plasma samples pooled from 6 COVID-19-infected patients,
571 while plasma from an uninfected individual was used as a negative control standard. To account for
572 variability between plates, the OD values were divided by the OD from the negative control from each plate,
573 run at a 1:50 dilution. To quantify the amount of anti-Spike Ig and anti-RBD Ig in the sample, end-point titers
574 were calculated as the linear interpolation of the inverse dilution at which the normalized OD value crossed
575 a threshold of 1, which was the maximum OD measured for the negative control.

576

577 *Flow cytometry*

578 Frozen PBMCs were thawed into 10 mL RPMI with 10% FCS, 1 mM EDTA + DNase I, washed,
579 and plated on 96 well laminar wash plates (Curiox). Subsequent washes were done using a laminar flow
580 plate washer (Curiox) in a BSL-2 hood, and all staining was done at room temperature. Cells were allowed
581 to settle for 40 minutes, washed, and stained with Live/Dead Blue (Invitrogen) in PBS for 20 minutes. Cells
582 were washed and incubated with monocyte blocker (Biolegend) and CCR7 BV421 (G043H7, Biolegend, 5

583 uL) for 10 minutes. Brilliant stain buffer plus (BD), CXCR3 PECy7 (G025H7, Biolegend, 5 uL), CXCR5
584 BV750 (RF8B2, BD, 1.2 uL), CCR6 BV711 (G034E3, Biolegend, 1.2 uL), and TCRgd PCPCeF710 (B1.1,
585 Thermo, 5 uL) were added for 10 minutes, and the remainder of extracellular antibodies (CD101 BUV563
586 (V7.1, BD, 5 uL), CD11b PCPCy5.5 (ICRF44, Biolegend, 0.6 uL), CD11c BUV661 (B-ly6, BD, 3.5 uL),
587 CD123 Super Bright 436 (6H6, Thermo, 3.5 uL), CD127 APC-R700 (HIL-7R-M21, BD, 6 uL), CD14
588 SparkBlue550 (63D3, Biolegend, 2.5 uL), CD141 BB515 (1A4, BD, 2.5 uL), CD15 Pacific Orange (VIMC6,
589 Thermo, 5 uL), CD16 BUV496 (3G8, BD, 0.6 uL), CD161 eFluor450 (HP-3G10, Thermo, 5 uL), CD19
590 SparkNIR685 (HIB19, Biolegend, 2 uL), CD1c AF647 (L161, Biolegend, 5 uL), CD25 PE (BC96, Biolegend,
591 10 uL), CD27 APC (M-T271, Biolegend, 5 uL), CD28 BV650 (CD28.2, Biolegend, 2.5 uL), CD3 BV510
592 (OKT3, Biolegend, 5 uL), CD38 APC-Fire810 (HIT2, Cytex/Biolegend, 1 uL), CD4 CFuor568 (SK3, Cytex,
593 1.2 uL), CD45 PerCP (2D1, Biolegend, 1.2 uL), CD45RA BUV395 (5H9, BD, 0.3 uL), CD45RO BV605
594 (UCHL1, Biolegend, 5 uL), CD56 BUV737 (NCAM16.2, BD, 3.5 uL), CD57 FITC (HNK-1, Biolegend, 1.2
595 uL), CD8 BUV805 (SK1, BD, 1.2 uL), CD86 BUV615 (BU63, BD, 5 uL), HLA-DR APCF750 (L243,
596 Biolegend, 2.5 uL), CD95 PECy5 (DX2, Biolegend, 0.6 uL), IgD BV480 (IA6-2, BD, 0.6 uL), IgM BV570
597 (MHM-88, Biolegend, 2.5 uL), PD-1 BV785 (EH12.2H7, Biolegend, 5 uL), TIM-3 PEDz594 (F38-2E2,
598 Biolegend, 5 uL)) were added for 45 minutes. Cells were washed and resuspended in 2%
599 paraformaldehyde for 30 minutes, and then washed and run on the Cytex Aurora spectral flow cytometer.
600 Data analyzed using FlowJo.

601

602 *Intracellular cytokine staining*

603 Frozen PBMCs were thawed into T cell media (RPMI with 10% FBS, 2 mM L-glutamine, 1 mM
604 sodium pyruvate, 50 uM 2-BME, 100 U/mL penicillin, 100 mg/mL streptomycin) washed, and allowed to
605 rest overnight. PepTivator SARS-CoV-2 peptide pools consisting of 15-mer sequences with 11 amino acids
606 overlap against the immunodominant sequence of the surface glycoprotein ("S"), and complete sequences
607 of the membrane glycoprotein ("M") and nucleocapsid phosphoprotein ("N") (all from Miltenyi Biotec) were
608 combined and used at 1 ug/mL, along with 0.5 ug anti-CD28/CD49D antibodies (clone L293/L25, BD
609 biosciences). The PepTivator SARS-CoV-2 peptide pools stimulate both CD8⁺ and CD4⁺ T cells. For
610 αCD3/CD28/CD49d, plates were coated overnight at 4 degC with 10 ug/mL anti-CD3 (clone SK7) in PBS,

611 and 0.5 ug anti-CD28/CD49d was added into the media with the PBMCs. 0.1 ug/mL phorbol myristate
612 acetate (PMA) and 1 ug/mL ionomycin were to the appropriate wells with PBMCs. The unstimulated
613 condition was also treated with 0.5 ug anti-CD28/CD49d. All conditions were incubated for 9 hours in the
614 presence of Golgiplug/Golgistop at manufacturer's recommended concentration (BD Biosciences). After
615 stimulation, 2 mM EDTA was added to the anti-CD3/CD28/CD49d wells and incubated for 15 minutes.
616 Cells were then transferred to a V-bottom 96 well plate for staining. Cells were stained with live/dead blue
617 (Invitrogen) in PBS for 15 minutes prior to adding monocyte blocker and CCR7 BV421 (G043H7, Biolegend,
618 5 uL) for 10 minutes. The remainder of the extracellular antibodies (TCRgd PCPCeF710 (B1.1, Thermo, 5
619 uL), CD3 BV510 (OKT3, Biolegend, 5 uL), PD-1 BV785 (EH12.2H7, Biolegend, 5 uL), CD56 BUV737
620 (NCAM16.2, BD, 3.5 uL), HLA-DR APCF750 (L243, Biolegend, 2.5 uL), CD20 Pacific orange (HI47,
621 Thermo, 5 uL), CD4 CFuor568 (SK3, Cytex, 1.2 uL), CD45 PerCP (2D1, Biolegend, 1.2 uL), CD19
622 SparkNIR685 (HIB19, Biolegend, 2 uL), CD8 BUV805 (SK1, BD, 1.2 uL), CD38 APC-Fire810 (HIT2,
623 Cytex/Biolegend, 1 uL), CD16 BUV496 (3G8, BD, 0.6 uL), CD45RA BUV395 (5H9, BD, 0.3 uL)) and brilliant
624 stain buffer plus (BD) in a total volume of 100 uL were added for 30 minutes, and cells were washed once.
625 Cells were resuspended in the fixation/permeabilization solution from eBioscience's FoxP3 / transcription
626 factor staining buffer for 30 minutes, washed, and incubated with intracellular antibodies in 100 uL (IFNy
627 AF488 (4S.B3, Biolegend, 5 uL), Granzyme AF532 (N4TL33, Thermo, 5 uL), IL-10 APC (JES3-19F1,
628 Biolegend, 5 uL), TNFa BV605 (MAb11, Biolegend, 5 uL), IL-2 BV650 (MQ1-17H12, Biolegend, 5 uL), Ki67
629 Pacific blue (Ki-67, Biolegend, 5 uL), IL-17A PE (BL168, Biolegend, 5 uL), IL-4 PEDz594 (MP4-25D2,
630 Biolegend, 5 uL), IL-6 PECy7 (MQ2-13A5, Biolegend, 5 uL), Perforin BV711 (dG9, Biolegend, 5 uL)) for 60
631 minutes in permeabilization buffer. Cells were washed 2x with permeabilization buffer prior to being
632 resuspended in FACS buffer and run on the Cytex Aurora. Data analyzed using FlowJo.

633

634 *ELISPOT*

635 PBMCs were thawed and washed with 10 mL RPMI prior to being plated in precoated human
636 IFN- γ ELISPOT plates (ImmunoSpot). Control MHC I and II peptide pools against common viral antigens
637 were used as positive controls (MHC I: 2 ug/mL of CEF peptide pool plus against CMV, EBV, and
638 influenza; MHC II: 50 ug/mL of CPI pool against CMV, influenza and parainfluenza; both from

639 ImmunoSpot). Wells with 0.1 ug/mL PMA and 1 ug/mL ionomycin were used as an additional positive
640 control. PBMCs in separate wells were stimulated with peptides from either the spike protein (“S”),
641 membrane glycoprotein (“M”) or nucleocapsid phosphoprotein (“N”) (all from Miltenyi Biotec) at 1 ug/mL.
642 SIYRYYGL (SIY peptide) was used as a negative (irrelevant) peptide control in each experiment with ≤ 1
643 spot seen in each irrelevant well. The total number of PBMCs recovered after thawing was divided into
644 12 wells, with PMA + Ionomycin controls plated at 10% of the cell density as other wells. Average cell
645 number per experimental well was 218,000, with a range of 50,000 - 750,000 cells for experimental wells.
646 Cells were incubated at 37°C with 5% CO₂ with activating stimuli for 18 hours in CTL-Test Medium
647 (ImmunoSpot) with 1% L-glutamine (Gibco) prior to developing plates per manufacturer’s recommended
648 procedure. Plates were scanned using ImmunoSpot analyzer and spots were counted using ImmunoSpot
649 7.0.17.0. Spots were normalized by dividing by number of cells plated per well * 100,000 to report spots
650 per 100,000 cells. The sum of the response in the S + M + N wells per 100,000 cells was reported as
651 IFN- γ spots / 100,000 cells.

652

653 *Viral load*

654 Leftover viral transport media from clinical nasopharyngeal swabs was stored at -80°C until
655 analysis. RNA was extracted using the Qiagen viral RNA mini kit following the manufacturer’s instructions,
656 with RNA eluted in 60 μ L of AVE buffer. Digital droplet PCR (ddPCR) was performed as previously
657 described⁶⁷. Briefly, a 20 μ L reaction was performed with 2 μ L N1/N2/RNaseP probe primer sets (IDT
658 #10006770), 5 μ L one-step ddPCR supermix, 2 μ L reverse transcriptase, 1 μ L 300 mM DTT, and 6 μ L
659 sample RNA. Amplification was performed under the following conditions: 25°C for 2 min, 50°C for 60 min,
660 95°C for 10 min, 45 cycles of [95°C for 30 seconds, 55°C for 1 min, then 98°C for 10 min], followed by
661 infinite hold at 4°C. Ramping speed was 2.5°C/s. Fluorescence was read using a QX200 droplet reader
662 (Bio-Rad) and analyzed with QuantaSoft software. Threshold of positivity defined in the manufacturer’s FDA
663 emergency use authorization approval was used (>0.1 copy number / μ L for either N1 or N2 and more than
664 2 positive droplets per reaction). Viral load is reported as the average of the N1 and N2 copy number / μ L.

665

666 *Multiplexed staining combining RNA-ISH and immunofluorescence staining for protein*

667 Simultaneous detection of RNA and protein antigens was performed by combining RNA *in situ*
668 hybridization (ISH) using the RNAScope® Multiplex Fluorescent Reagent Kit v2 assay together with
669 antibody-based immunofluorescence staining, according to the manufacturer's integrated co-detection
670 protocol (Advanced Cell Diagnostics, ACD). Briefly, formalin-fixed paraffin-embedded (FFPE) lung tissue
671 sections were baked for 30 min at 60° C, deparaffinized by submerging in xylenes for 5 mins twice. The
672 sections were rehydrated in 100% ethanol for 1 min twice, air dried, treated with RNAScope® hydrogen
673 peroxide for 10 min, and rinsed with distilled water. Target retrieval was performed in a TintoRetriever
674 Pressure cooker (Bio SB) using 1x Co-Detection Target Retrieval solution at 98-102° C for 15 min. Slides
675 were rinsed in distilled water and 1x Phosphate-Buffered Saline Tween buffer (PBST). The tissue sections
676 were blocked with Co-Detection antibody diluent (ACD) and incubated with anti-TTF1 antibody (SPT24,
677 BioCare Medical) overnight at 4° C, washed in PBS-T buffer, incubated in 10% Neutral Buffered Formalin
678 for 30 min at RT, and washed in PBS-T. Tissue sections were treated with RNAScope® Protease plus at
679 40° C for 30 min and rinsed in distilled water. *In situ* hybridization was performed according to the
680 RNAScope® assay protocol. Briefly, sections were incubated with RNA probe mix and hybridized at 40° C
681 for 2 hours. The following RNAScope® probes were used: V-nCoV2019-S-C1 (specific for SARS-CoV-2, S
682 gene encoding the spike protein), Hs-IL-6-C4, Hs-CCL2-C2. Signal amplification was performed using the
683 RNAScope Multiplex FL v2 AMP reagents, AMP1 (30 min, 40° C), AMP2 (30 min, 40° C), and AMP3 (15
684 min, 40° C), sequentially. Development of the horseradish peroxidase (HRP) signal was performed
685 according to the manufacturer's protocol. Fluorescent labeling of the IL-6 and CCL2 RNA probes was
686 performed using OPAL 620 dye (Akoya Biosciences), while labeling of the SARS-CoV-2 RNA probe was
687 performed using Opal 540 dye. The TTF1 primary antibody was detected with HRP-conjugated secondary
688 antibody (Opal Polymer HRP Ms + Rb, Perkin Elmer) and Opal 690 dye. Subsequent staining on the same
689 sections was performed with an antibody against CD45 (Leukocyte Common Antigen Cocktail: PD7/26/16
690 and 2B11, BioCare Medical) and detected with HRP-conjugated secondary antibody and Opal 520 dye.
691 After all targets were labeled, the sections were incubated with DAPI solution for 5 min at room temperature
692 and mounted in ProLong Diamond Antifade Mountant (Invitrogen). Co-staining for IL-6 RNA and
693 macrophages was performed using RNAScope® probe Hs-IL-6, which was fluorescently labeled with OPAL
694 690 dye, and an antibody against either CD68 (Clone KP1, BioCare Medical; diluted in Da Vinci Green

695 diluent) or CD163 (Clone 10D6, BioCare Medical; diluted in Renoir Red diluent) and detected with HRP-
696 conjugated secondary antibody (Opal Polymer HRP MS+ RB) and OPAL 540 dye. Slides were scanned
697 using the Vectra Polaris imaging platform and Phenochart software (PerkinElmer). For quantitative analysis,
698 up to 200 representative fields of view for each tissue section were acquired at 40x magnification as
699 multispectral images. Image analysis and cell phenotyping were performed using a supervised machine
700 learning algorithm within the Inform 2.3 software (PerkinElmer), which assigned trained phenotypes and
701 cartesian coordinates to cells.

702

703 *Clinical data warehouse*

704 Clinical data was exported through a clinical data warehouse and was also abstracted by a clinical
705 data manager into a standardized RedCap database. Patients with a history of active cancer, organ
706 transplantation were excluded. Medications administered were searched from the clinical data warehouse
707 to find and exclude patients receiving steroids, immunosuppressants, chemotherapy, or immunotherapy
708 agents. Patients with positive blood cultures were identified and excluded. Patients noted to have alternative
709 causes of cardiovascular shock or a pneumothorax were excluded as indicated in Table 1. Outpatients did
710 not routinely have FiO₂ documented, so outpatients were all categorized as mild with an S/F ratio set to
711 476 (equivalent to SpO₂ 100% on room air).

712

713 *Statistics and Data processing*

714 Throughout the paper, boxplots show the medians (middle line) and the first and third quartiles
715 (upper and lower bounds of the boxes). Significance of comparisons from boxplots were determined by
716 two-sided Mann Whitney Wilcoxon test and significance is expressed as p-values, shown as asterisks (*,
717 $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$). All replicates are from distinct samples. Correlations between
718 clinical and research parameters were analyzed using pairwise Spearman's correlation coefficients and
719 were visualized with R package corrplot⁶⁸. Correlation was quantified by a color scale, the significance of
720 the correlation was labeled with asterisks, and boxes with a thick black border represent a false-discovery
721 rate (FDR) <0.05.

722 To determine which features were predictive of disease severity, the Random Forest R package
723 randomForest⁶⁹ was used and area under the ROC curve (AUC) calculated. A 3-fold cross-validation was
724 used and the mean AUC on the test data set was presented. Models were trained for early phase (D0-D9),
725 late phase (D10-D30), and all timepoints (D0-D30) separately. Correlation plots and the machine learning
726 algorithm were processed using R studio (R 3.6.1).

727 Flow cytometry data were processed using FlowJo V10.7.1. Graphs were created and statistics
728 performed using either GraphPad Prism v9.0.0 or R 4.0.3 (R Core Team, 2020). R packages used include
729 Formula⁷⁰, ggpmisc⁷¹, ggpubr⁷², ggsignif⁷³, gridExtra⁷⁴, Hmisc⁷⁵, lubridate⁷⁶, magrittr⁷⁷, patchwork⁷⁸,
730 readxl⁷⁹, reticulate⁸⁰, rstatix⁸¹, scales⁸², stringr⁸³, survival⁸⁴, tidyverse⁸⁵, writexl⁸⁶, zoo⁸⁷, and corplot⁶⁸.

731

732 *Data Availability*

733 Raw .fcs files are available at (will be deposited prior to publication). The datasets generated during
734 and/or analysed during the current study are available from the corresponding author on reasonable
735 request.

736

737 *Code Availability*

738 Full reproducible code for data processing is available at
739 <https://github.com/jovianyu/covid19biobank> .

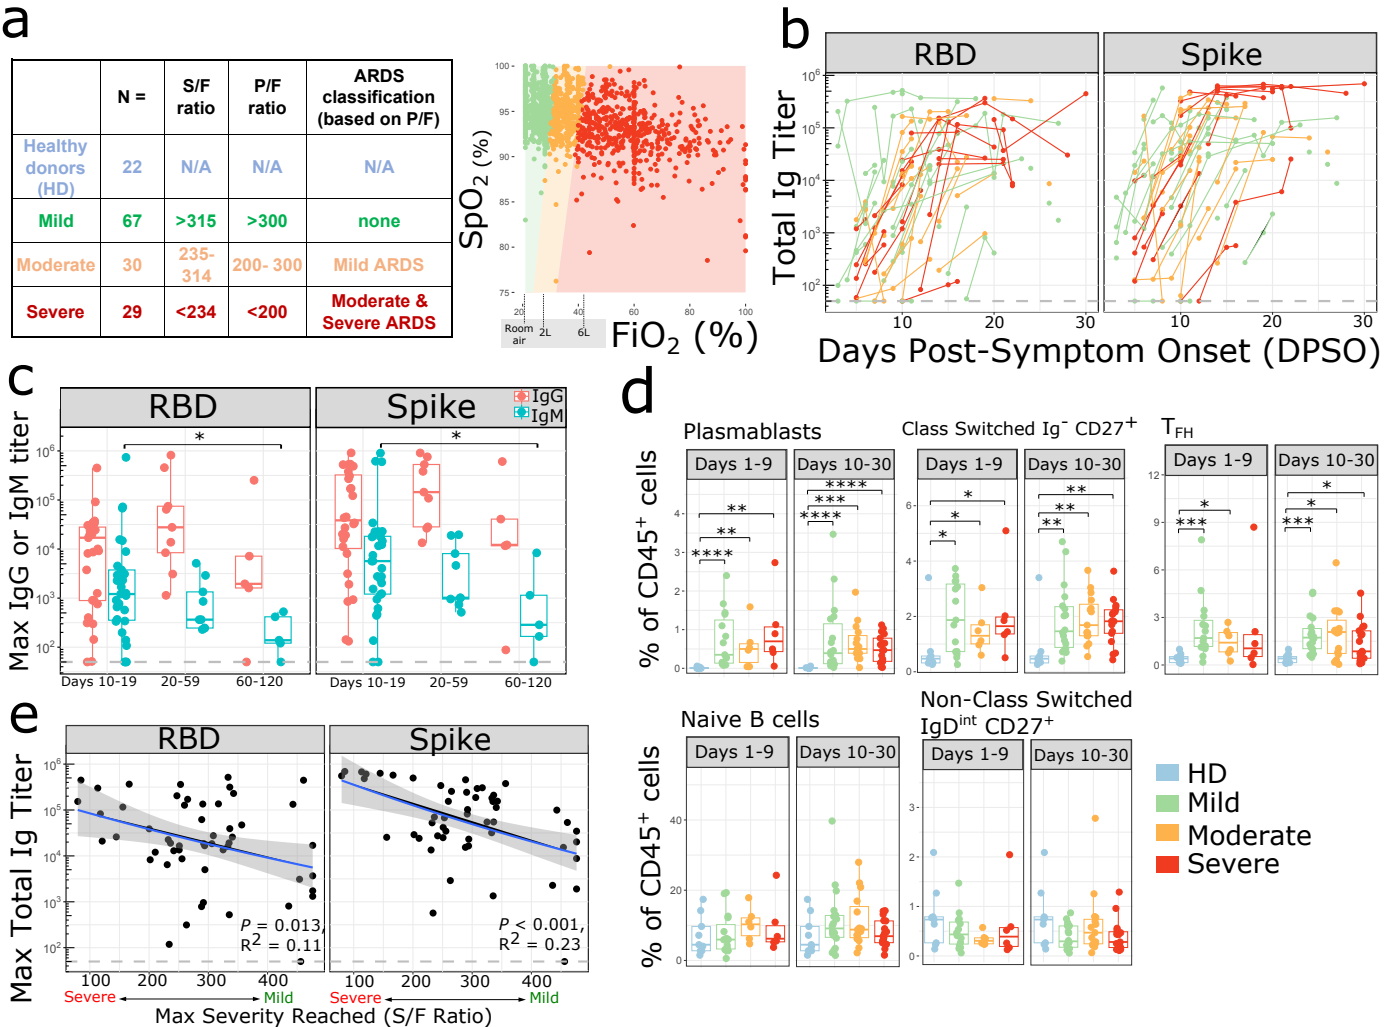

Figure 1: Activated B cells and antibody responses are induced within 10 days of SARS-CoV-2 symptom onset (a) Number (N) of patients in each disease severity classification. The table describes the relationship between SaO₂/FiO₂ (S/F), PaO₂/FiO₂ (P/F) ratio and ARDS classes for mild, moderate and severe categories based on Rice et al¹⁵. The relationship between SpO₂ and FiO₂ is depicted on the right. Each dot represents an individual S/F ratio calculated based on the simultaneous oxygen saturation and FiO₂ recorded for hospitalized patients; all available timepoints per day per patient are shown. Oxygen delivery categories are labelled on the X axis. Colored shaded areas indicate S/F ratios which correspond to mild (green), moderate (orange) and severe (red) disease severity categories. (b) Serum SARS-CoV-2 total Ig antibody levels (RBD and Spike) in (n=68) PCR+ patients over time expressed as days post symptom onset (DPSO). Samples from individual patients are connected by lines, and colored by disease severity (mild in green, moderate in orange, severe in red). The dashed line indicates the max titer of a pool of negative controls, used as the threshold for positivity. Samples post receipt of convalescent plasma transfusion were excluded from this and all antibody analyses. (c) Maximum serum SARS-CoV-2 IgG (red) and IgM (turquoise) antibody levels (RBD and Spike) in PCR+ patients during acute phase of infection (day 10-19) (n=31), recovery (day 20-59) (n=9), and late recovery (day 60-120) (n=5), where day is DPSO. Data from the pre-humoral phase (<day 10) is excluded. (d) Mean populations of immune cell subsets involved in the humoral response, plotted as % of CD45⁺ cells, during the early phase (days 1-9 from symptom onset) and late phase (days 10-30 from symptom onset) of disease in COVID-19 infection compared to non-infected healthy donor controls (HD). Each dot represents the average of measurements during each phase of disease from an individual subject (early phase: mild, n=15; moderate, n=6; severe disease, n= 6 and late phase: mild, n=18; moderate, n=15; severe, n=17; non-infected healthy controls, n=9). The boxplots show the medians (middle line) and the first and third quartiles (upper and lower bounds of the boxes). (c,d) Significance was determined by two-sided Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, p ≤ 0.05; **, p ≤ 0.01; ***, p ≤ 0.001, ****, p ≤ 0.0001). (e) Linear regression shown for disease severity expressed as S/F ratio and maximum anti-SARS-CoV-2 (RBD and Spike) total Ig antibody titers from days 10-30 in (n=53) PCR+ patients. Shaded areas represent 95% confidence interval. Ig titers from the pre-humoral phase (<day 10) were excluded.

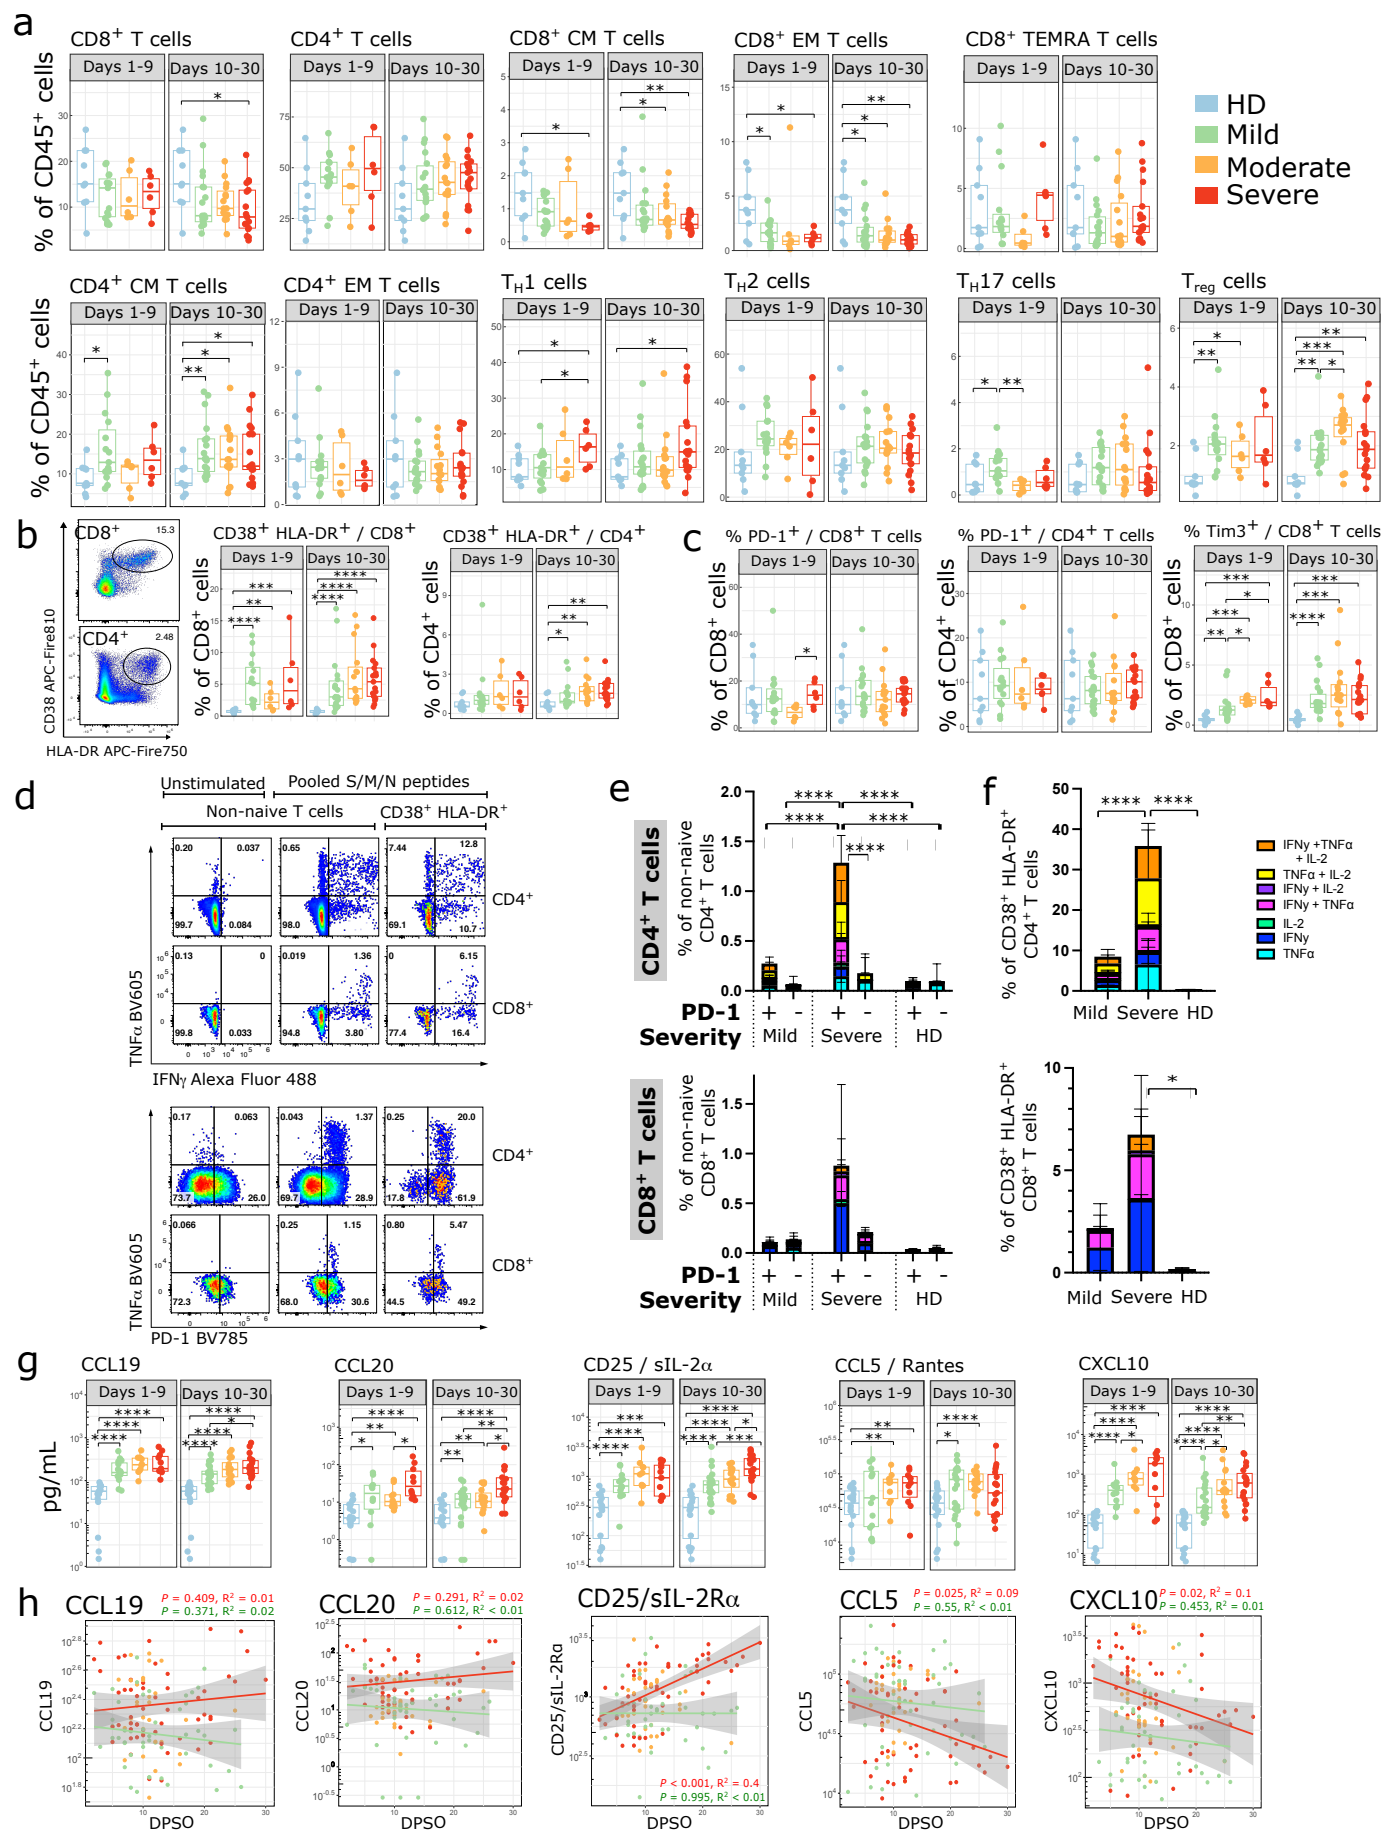

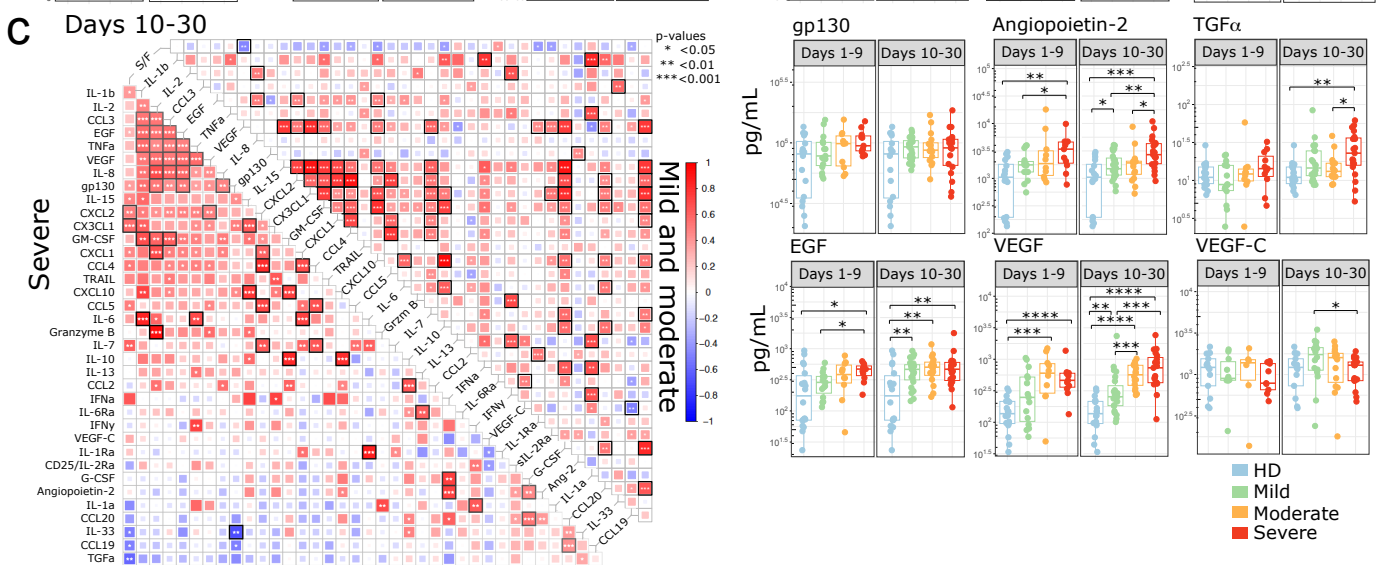

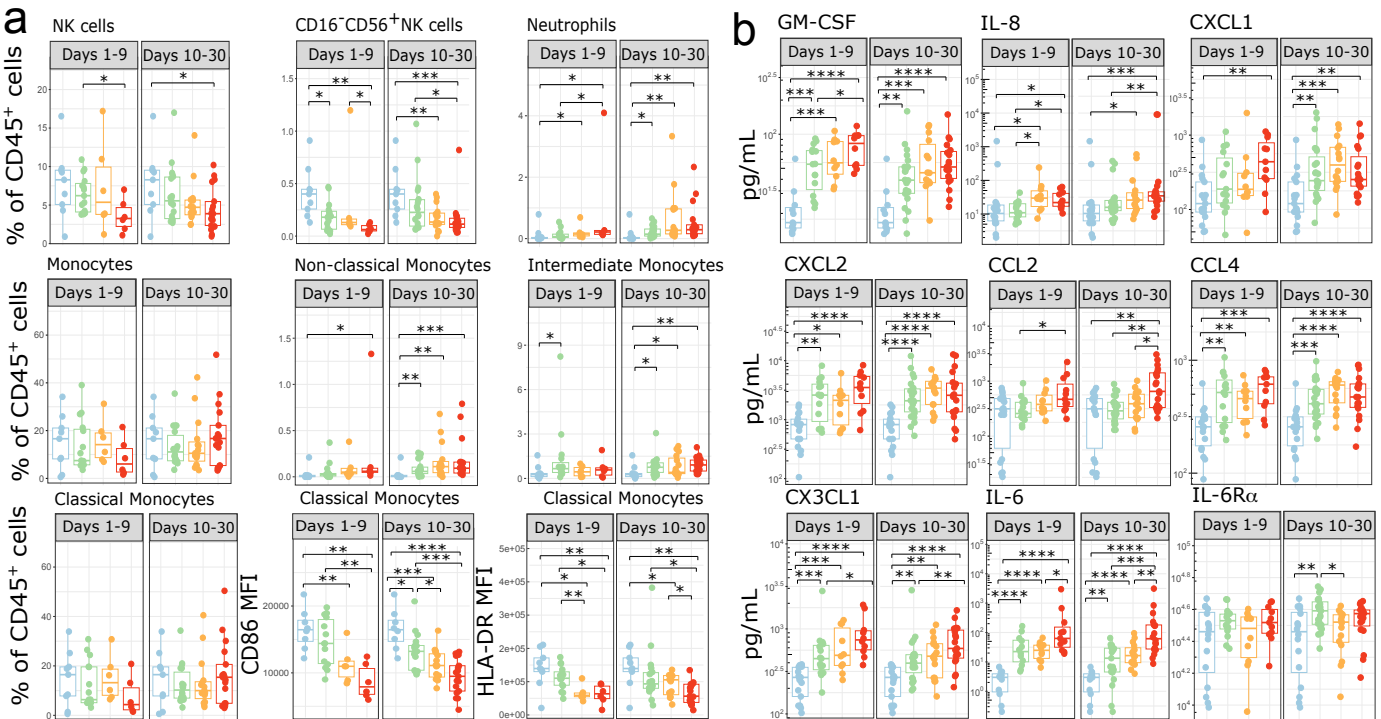

Figure 2

Figure 2: SARS-CoV-2 infection elicits a robust expansion of activated polyfunctional T cells (a-c) Proportion of immune cell subsets related to adaptive immune responses are shown as a percentage of either live CD45+ cells, live CD4+ cells, or live CD8+ cells, as indicated. Where multiple timepoints within the early (D1-9) or late (D10-30) phase per patient were available, the mean was taken and each patient is represented by one dot per time phase. n = 9 for HD, n = 15, 6, 6 for mild, moderate, and severe respectively in the early phase, and n = 18, 15, 17 for mild, moderate, and severe in the late phase. (b, left) Representative flow cytometry plots showing CD38+ HLA-DR+ subsets. (d-f) PBMCs from D11-25 DPSO were stimulated with a combined pool of peptides from the S, M and N proteins for 9 hours and stained for intracellular cytokine production. Background activity in unstimulated wells was subtracted from stimulated wells; negative values after subtraction were set to 0. Representative flow cytometry plots are shown for TNF α /IFN- γ (d, upper panels) and TNF α /PD-1 (d, lower panels) staining. The percentage of cells producing various combinations of IFN- γ , TNF α , and IL-2 were reported for CD4+ and CD8+ non-naive (e) and CD4+ and CD8+ CD38+HLADR+ cells (f). (e,f) Comparisons between groups were done by summing the total cytokine production in each column and performing a 2-way ANOVA with Sidak's multiple comparisons test. Error bars represent mean \pm SD for each cytokine subset. HD n = 9; mild n = 8; severe n = 7. Wells with <50 CD38+HLA-DR+ cells were excluded from that subset analysis, leaving n = 9 / 7 / 6 HD/mild/severe for CD4+CD38+HLA-DR+ and n = 9 / 8 / 6 HD/mild/severe for CD8+CD38+HLA-DR+. (g) Peak cytokine and chemokine levels related to T cell activation and survival are shown during the early phase (days 1-9 from symptom onset) and late phase (days 10-30 from symptom onset) of disease in SARS-CoV-2 infection compared to non-infected healthy controls. Each dot represents maximum value per individual subject during each phase of disease (early phase: mild, n=15; moderate, n=10; severe, n= 11 and late phase: mild, n=23; moderate, n=16; severe, n= 19 and non-infected healthy controls, n=18). Samples from patients post receipt of tocilizumab (which directly modulates cytokine levels) were excluded from this and subsequent cytokine analyses. (h) Kinetics of cytokine expression over time (days post symptom onset) from mild (green, n = 33), moderate (orange, n = 19), and severe (red, n = 23) patients. Multiple timepoints per patient plotted when available. Linear regression for cytokine values over time in severe (red) and mild (green) patients shown. Shaded areas represent 95% confidence interval. (a-c, g) Significance was determined by two-sided Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, p \leq 0.05; **, p \leq 0.01; ***, p \leq 0.001, ****, p \leq 0.0001).

Figure 3

Figure 3: Innate immune changes in SARS-CoV-2 infection (a) Immune cell subsets related to the innate immune response are shown. Boxplots show percentages of each cell population out of live CD45+ cells or MFI of indicated markers. Where multiple timepoints within the early (D1-9) or late (D10-30) phase per patient were available, the mean was taken and each patient is represented by one dot per time phase. $n = 9$ for HD, $n = 15, 6, 6$ for mild, moderate, and severe, respectively in the early phase, and $n = 18, 15, 17$ for mild, moderate and severe in the late phase. (b) Peak cytokine and chemokine levels are shown during the early phase (days 1-9 from symptom onset) and late phase (days 10-30 from symptom onset) of disease in SARS-CoV-2 infection compared to non-infected healthy controls. Each dot represents maximum value per individual subject during each phase of disease (early phase: mild, $n=15$; moderate, $n=10$; severe, $n= 11$ and late phase: mild, $n=23$; moderate, $n=16$; severe, $n= 19$ and non-infected healthy controls, $n=18$). (c) Correlations between cytokines from days 10-30 for COVID-19 patients were calculated and clustered hierarchically. S/F ratio is fixed as the first column for comparison. Samples were stratified by disease severity. Spearman correlation coefficients were quantified by the scale of color and size of colored squares; significance of the correlation is labeled with * ($P < 0.05$), ** ($P < 0.01$), and *** ($P < 0.001$). Black border represents a false-discovery rate (FDR) < 0.05 (d) Kinetics of cytokine expression over time (days post symptom onset) from mild (green, $n = 33$), moderate (orange, $n = 19$), and severe (red, $n = 23$) patients. Multiple timepoints per patient plotted when available. Linear regression for cytokine values over time in severe (red) and mild (green) patients shown. (e) Peak individual levels of CCL2 and IL-6 are shown as linear correlation with the sum of days each patient spent hospitalized with a moderate or severe S/F ratio, termed “total non-mild days”. Each dot represents maximum cytokine value per individual subject; maximal disease severity indicated by color (moderate [orange], $n=20$; severe [red], $n= 19$, deceased [black], $n= 3$). (d-e) Shaded areas represent 95% confidence interval. (f) The top 10 ranked immune parameters associated with severity per the Random Forest model are tabulated for early phase (days 1-9 from symptom onset) and late phase (days 10-30 from symptom onset) and all time-points (day 1-30 from symptom onset). The linear regression R^2 value for each variable is shown in parenthesis, indicating the amount of variation in disease severity that can be explained by this variable alone. +/- denotes direction of association, + indicating the higher the variable the higher (i.e., less severe) the S/F ratio, and - indicating the higher the variable the lower the S/F ratio (i.e. the more severe the disease). Sensitivity, Specificity and AUC are shown. (a-b) Significance was determined by two-sided Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$, ****, $p \leq 0.0001$).

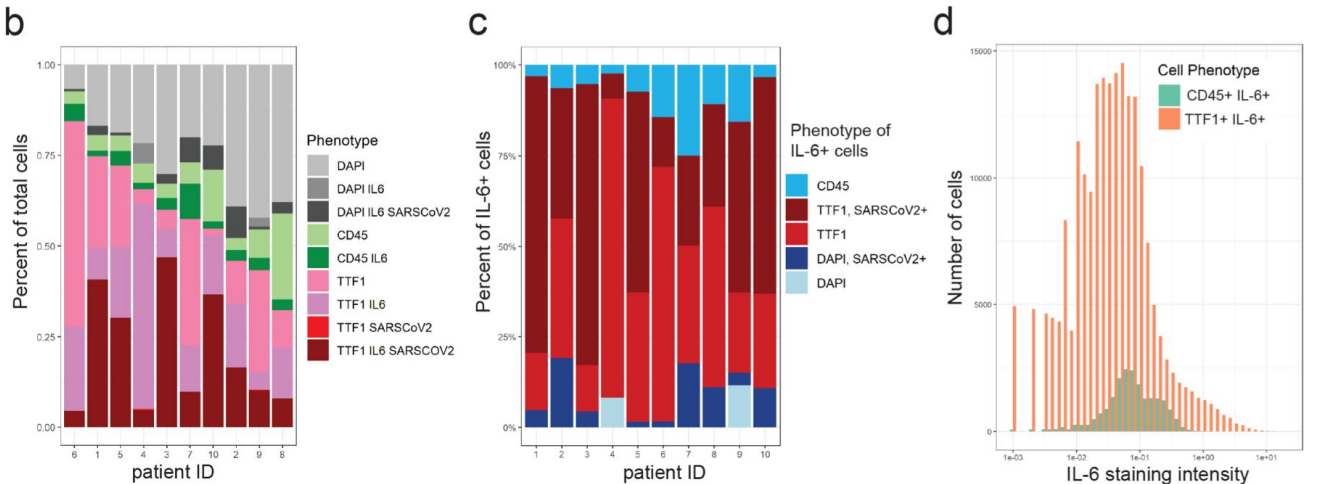

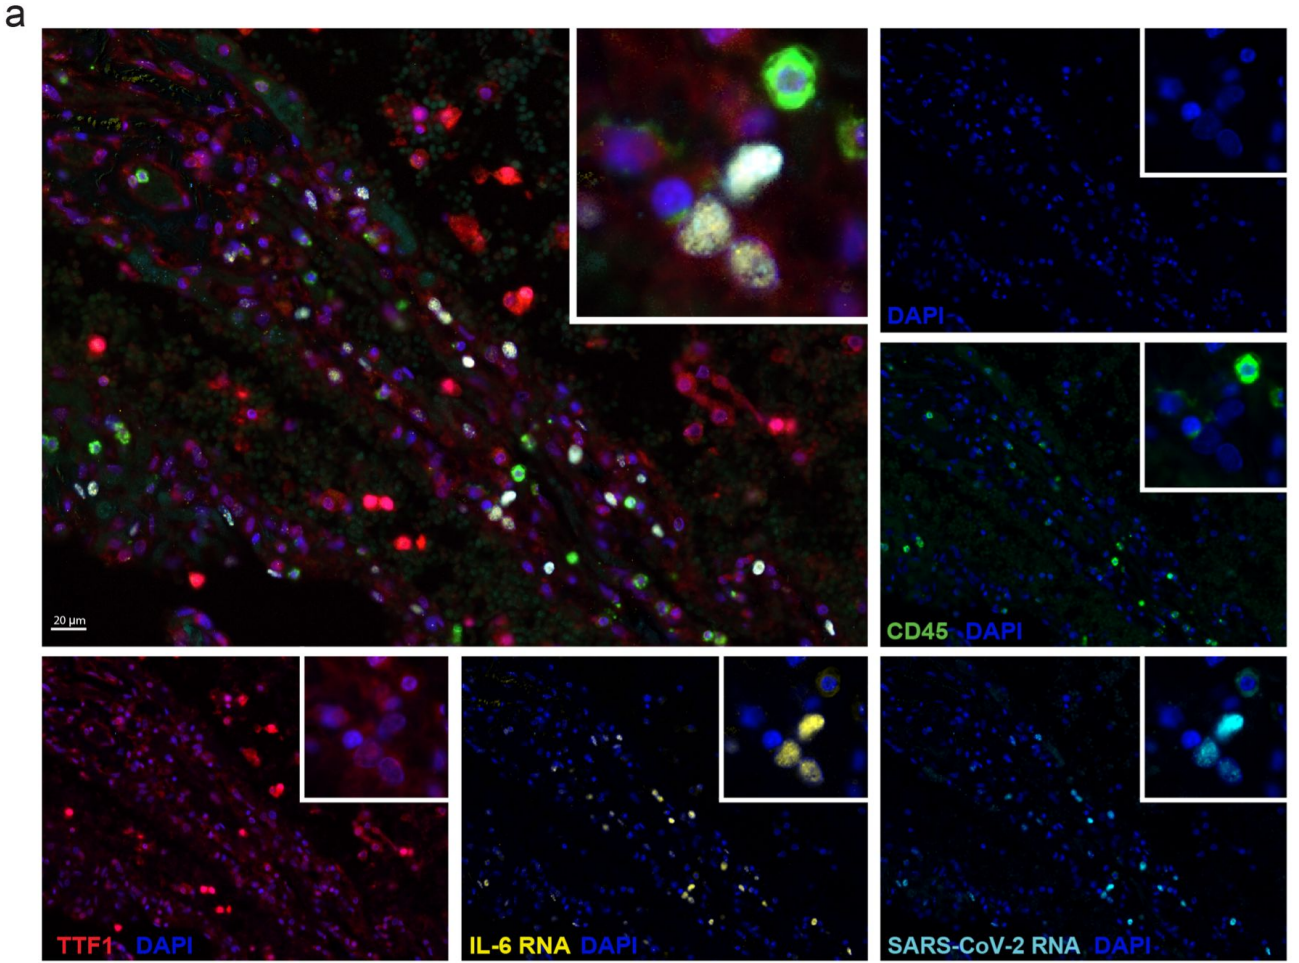

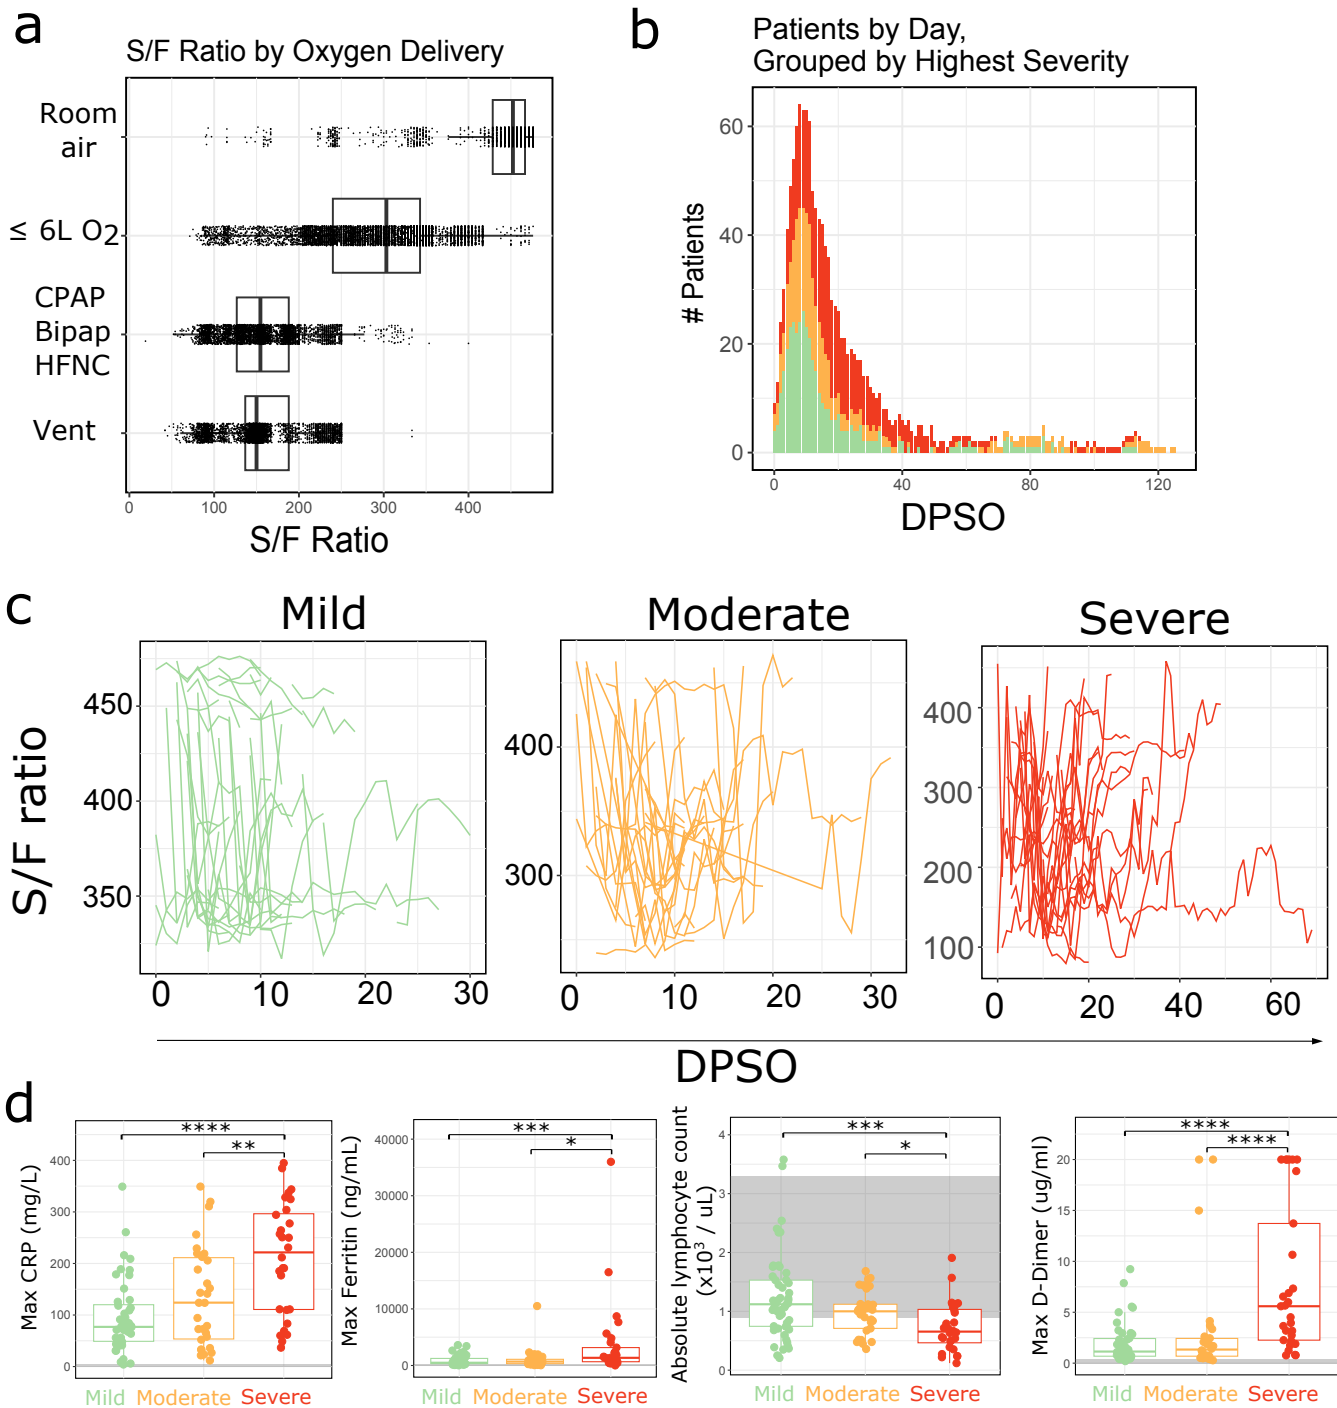

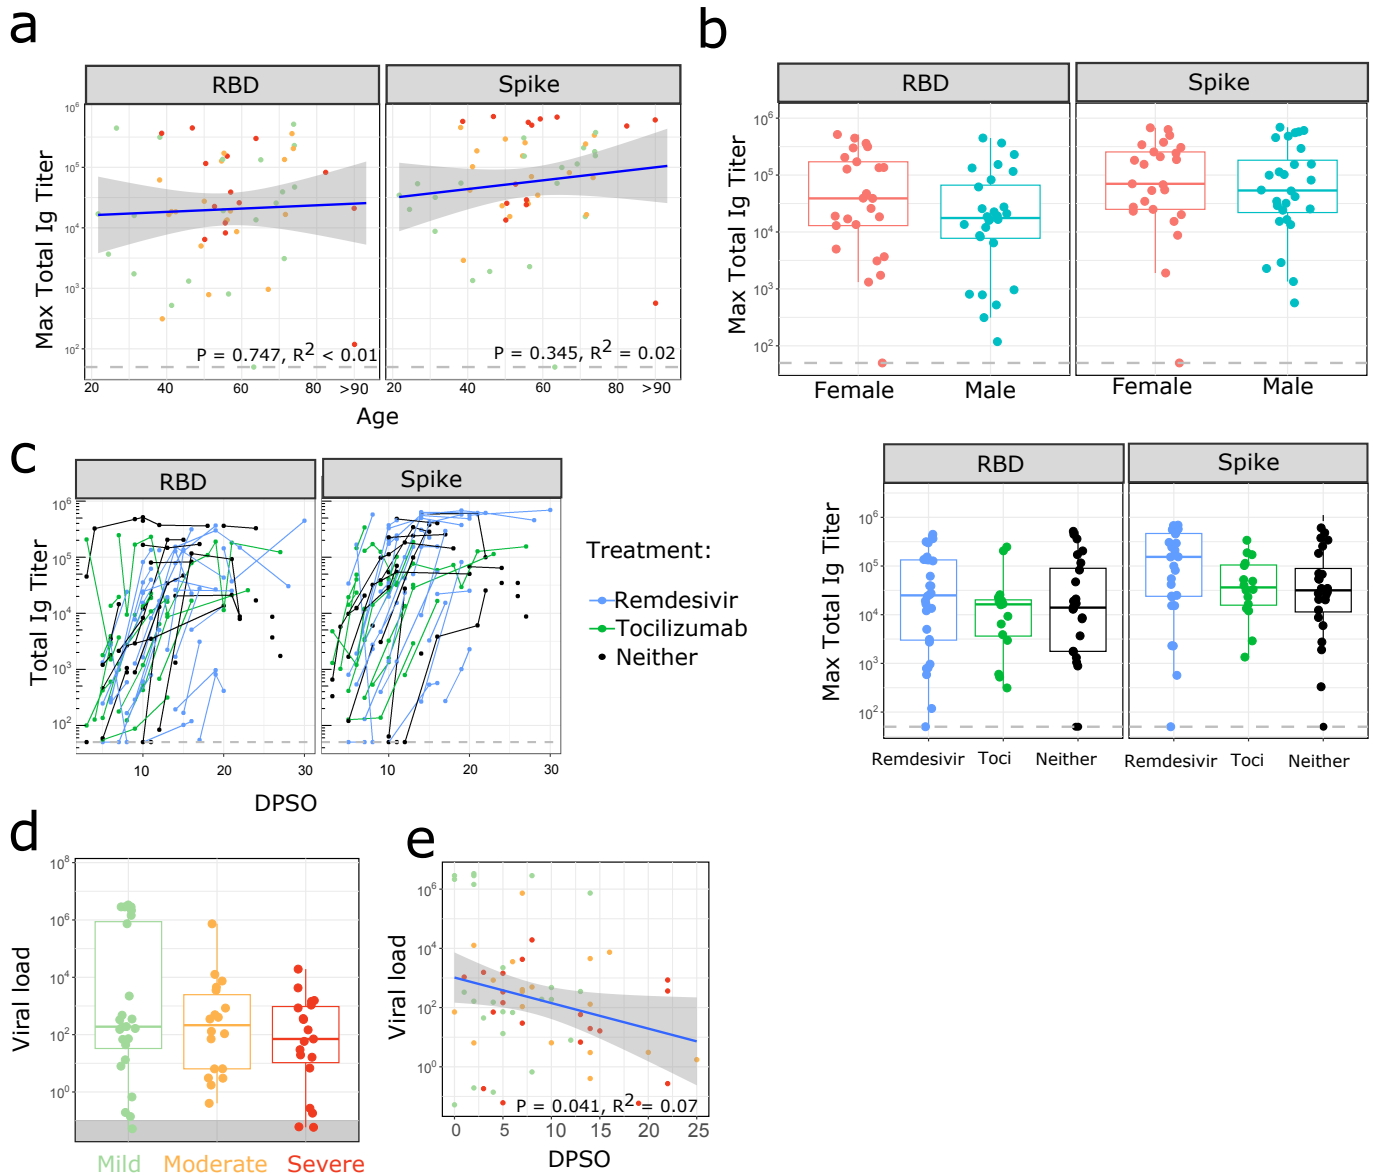

Figure 4: Lung epithelial cells predominantly express IL-6 in lung autopsy tissue in fatal COVID-19. Autopsy lung sections from 10 fatal COVID-19 cases were simultaneously stained for SARS-CoV-2 RNA, IL-6 mRNA, TTF1+ pneumocytes, and CD45+ leukocytes using RNA-ISH combined with multispectral immunofluorescence staining for protein. (a) Representative staining for TTF1 (red), CD45 (green), IL-6 RNA (yellow), SARS-CoV-2 RNA (light blue), and nuclear DAPI counterstain (blue); each stain shown separately and merged. Multispectral images were acquired at 40x magnification. Overlaying high-power images showing SARS-CoV-2 infected TTF1+ pneumocytes expressing high levels of IL-6. (b) Bar plots showing the phenotype composition of cell populations in each autopsy lung specimen. (c) Bar plots showing the phenotype composition of IL-6+ cells in each autopsy lung specimen. (d) Histogram displaying the frequency distribution of mean staining intensity for IL-6 between TTF1+IL-6+ cells (red) versus CD45+ IL-6+ cells (aqua). Cumulative data from all patients shown.

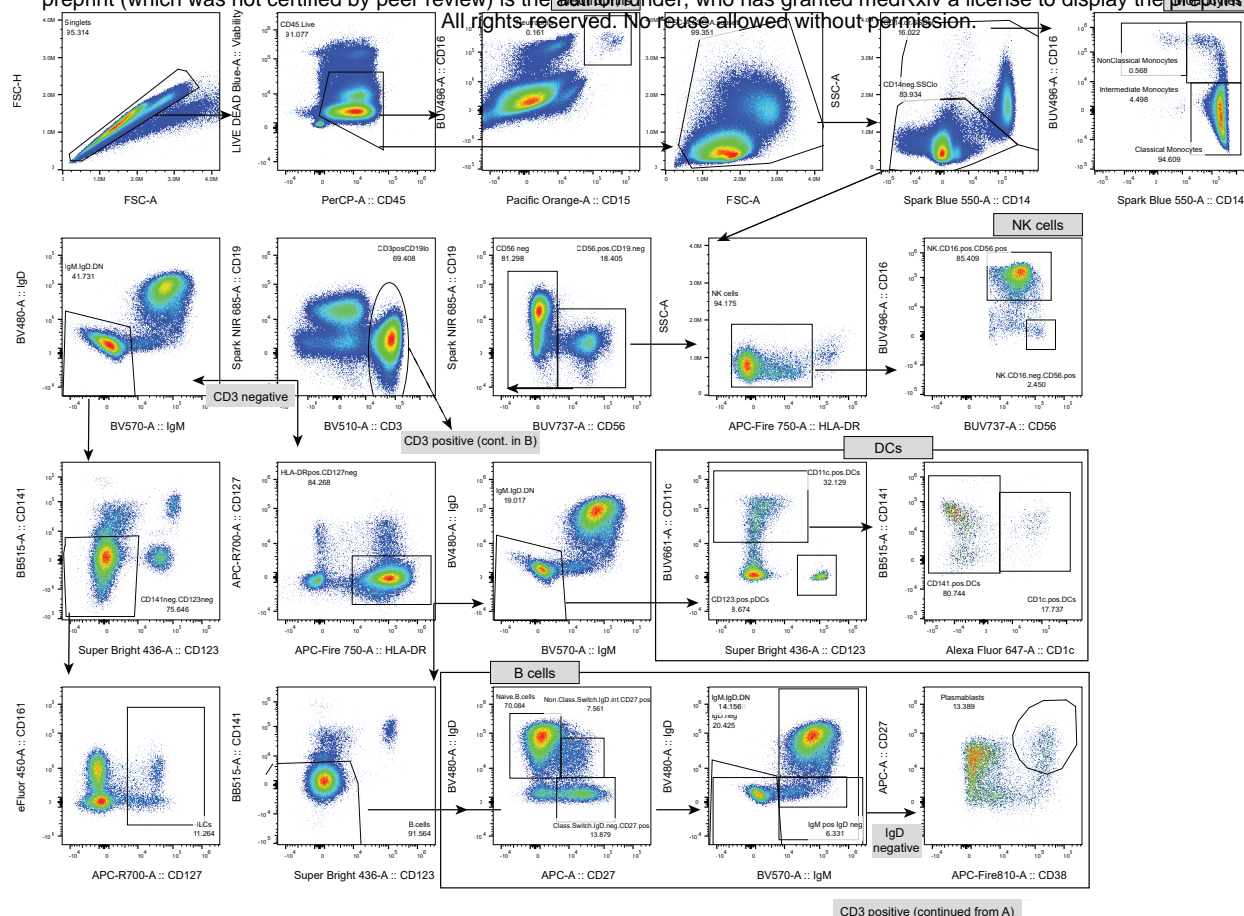

Supplemental Fig 1: Clinical features of study cohort (a) The relationship between S/F ratio and oxygen delivery is depicted. All values during initial admission for all patients ($n = 126$) are included. Each dot represents an individual S/F ratio, and multiple ratios per patient per day are plotted. This includes individual values with the $SpO_2 < 88\%$ which preceded an increase in the patient's clinical oxygenation requirement. (b) Stacked histogram showing number of patients hospitalized versus days post symptom onset; each patient is represented multiple times based on duration of hospitalization. Disease severity is indicated by color (mild - green, moderate - orange, severe - red). (c) Mean daily S/F ratio is shown for mild, moderate and severe patients over time, with data from the same patients connected by lines. (d) Maximum CRP, Ferritin, D-Dimer and nadir of absolute lymphocyte count are shown for mild, moderate, and severe patients. Each dot represents the maximum or nadir value for each patient over the course of their initial hospitalization. The grey line indicates the maximum normal value. The grey block background indicates the normal reference range. Significance was determined by two-sided Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$, ****, $p \leq 0.0001$).

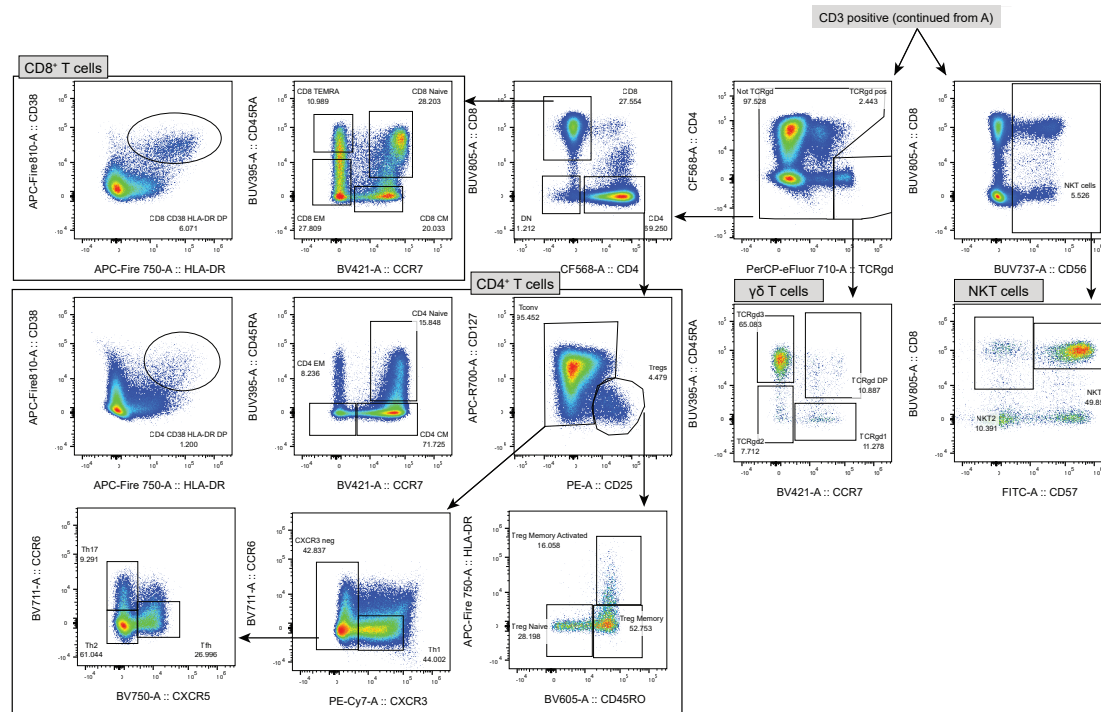

Supplemental Fig 2: Antibody response does not differ based on age, gender, or treatment with remdesivir or tocilizumab (a) Maximum serum SARS-CoV-2 total Ig antibody levels (RBD and Spike) between D10-30 in PCR+ patients ($n = 53$) are shown by age. Disease severity indicated by color (green = mild, orange = moderate, red = severe). (b) Maximum serum SARS-CoV-2 total Ig antibody levels (RBD and Spike) between D10-30 in PCR+ patients are shown for females (F, $n=25$) and males (M, $n=28$). (c) Serum SARS-CoV-2 total Ig antibody levels (RBD and Spike) in PCR+ patients receiving remdesivir (blue, $n=28$), tocilizumab (green, $n=16$), or neither (black, $n=24$). Antibody levels over time shown in the left panel, and maximum titer per patient shown in the right panel. (d-e) Viral titers were obtained by ddPCR on leftover viral transport medium. Disease severity indicated by color (green = mild, $n=24$; orange = moderate, $n=18$; red = severe disease, $n=19$) patients. In d), the grey shaded area denotes negative results. (e) Linear correlation between day post symptom onset and viral load measured by ddPCR, disease severity is indicated by dot color. (a,e) Shaded areas represent 95% confidence interval. (b,c,d) Groups were compared with two-sided Mann Whitney Wilcoxon test and no significant differences were seen.

Supplemental Fig. S3

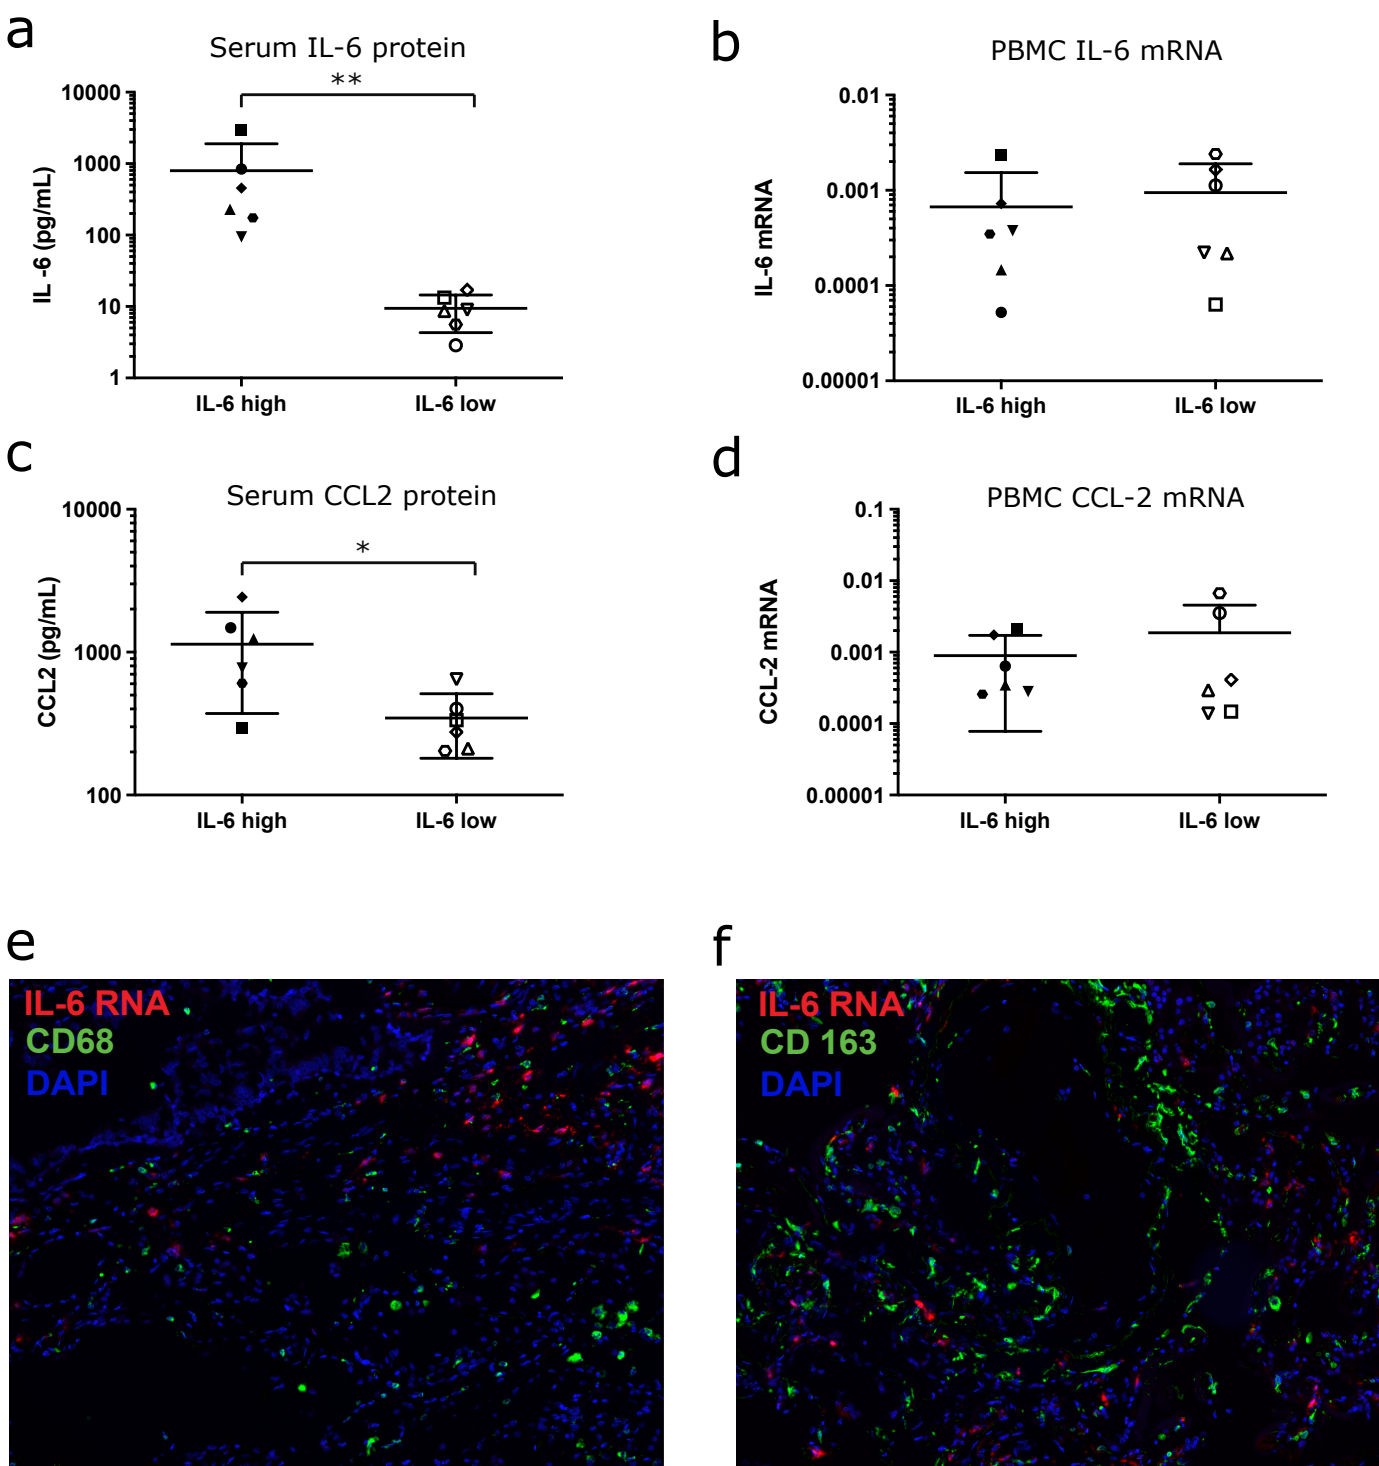

Supplemental Fig 3: Flow cytometry gating strategy. (a) Gating for extracellular flow cytometry for monocytes, dendritic cells, B cells, and NK cells. (b) Gating for extracellular flow cytometry for T cells, $\gamma\delta$ T cells, and NKT cells. (c) Flow cytometry gating for intracellular cytokine stimulation assays.

Supplemental Fig 4: SARS-CoV-2 infection is associated with increased activation and functionality of CD4+ and CD8+ T cells. (a-b) Boxplots show MFI of indicated markers in each CD4+ (a) or CD8+ (b) T cell population. Where multiple timepoints within the early (D1-9) or late (D10-30) phase per patient were available, the mean was taken and each patient is represented by one dot per time phase. n = 9 for HD (blue), n = 15, 6, 6 for mild (green), moderate (orange), and severe (red) respectively in the early phase, and n = 18, 15, 17 for mild, moderate and severe in the late phase. (c) UMAP projections of live, CD45+ CD3+ cells from samples between D11-17 DPSO (equal numbers of cells sampled from n=7, 7, 7, 7 HD, mild, moderate, and severe patients, respectively) with FlowSOM clusters overlaid. (d) Marker expression in each FlowSOM cluster shown. (e) The percentage of each cluster derived from HD (blue), mild (green), moderate (orange) or severe (red) patients. (f) PBMCs were stimulated with peptides from the S, M, or N proteins in separate wells for 18 hours and IFN- γ production measured by ELISPOT. Response to S, M, and N peptides was summed and normalized per 100,000 cells plated. IFN- γ ELISPOT response shown as a linear correlation with DPSO with disease severity indicated by color with shaded area representing 95% confidence interval (top panel) and as a boxplot by disease severity (bottom panel); n = 10, 17, 18 in mild (green), moderate (orange), and severe (red), respectively. (g) Cytokine production after stimulation with pooled peptides from the S, M and N proteins, α CD3/CD28/CD49d antibodies, or PMA and ionomycin is shown for each individual patient. Background activity in unstimulated wells was subtracted from stimulated wells. The percentage of cells producing various combinations of IFN- γ , TNF α , and IL-2 were reported. HD: n = 9 for SMN stimulation, n = 8 for α CD3/CD28/CD49d and PMA+ionomycin stimulation; mild n = 8; severe n = 7. (h) Maximum cytokine and chemokine levels related to T cell homeostasis are shown during the early phase (days 1-9 from symptom onset) and late phase (days 10-30 from symptom onset) of disease in SARS-CoV-2 infection compared to non-infected healthy controls. Each dot represents maximum value per individual subject during each phase of disease (early phase: mild, n=15; moderate, n=10; severe, n= 11 and late phase: mild, n=23; moderate, n=16; severe, n= 19 and non-infected healthy controls, n=18). (a, b, f, h) Significance was determined by two-sided Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, p \leq 0.05; **, p \leq 0.01; ***, p \leq 0.001, ****, p \leq 0.0001).

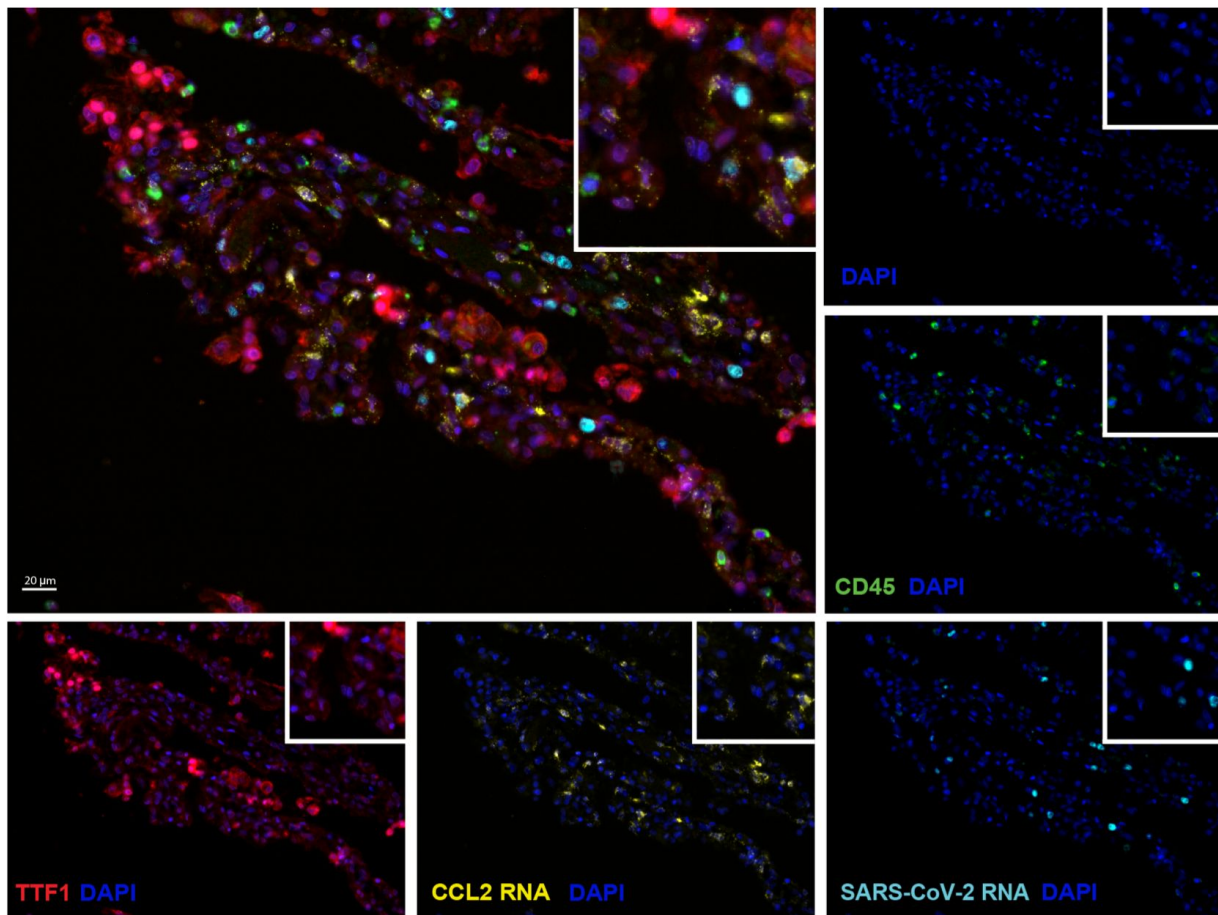

Supplemental Fig 5: Induction of innate immune responses in SARS-CoV-2 infection. (a,b) Immune cell subsets related to the innate immune response are shown. Boxplots show percentages of each cell population out of live CD45+ cells or MFI of indicated markers on dendritic cells, monocytes or neutrophils. Where multiple timepoints within the early (D1-9) or late (D10-30) phase per patient were available, the mean was taken and each patient is represented by one dot per time phase. $n = 9$ for HD, $n = 15, 6, 6$ for mild, moderate, and severe respectively in the early phase, and $n = 18, 15, 17$ for mild, moderate and severe in the late phase. (c) The MFI of HLA-DR on classical, intermediate, and non-classical monocytes is shown as a linear regression with peak serum GM-CSF levels in $n = 24, 13, 18$ mild (green), moderate (orange), and severe (red) patients respectively. (d) Linear regression is shown for peak serum IL-6 and peak clinical CRP level. Each dot represents the maximum value per individual subject during the disease (mild, $n=17$; moderate, $n=18$; severe, $n=21$). (e) Linear correlations between peak serum gp130 or IL-6R α levels versus DPSO in severe (red) and mild (green) patients; disease severity is indicated by color in mild (green, $n = 23$), moderate (orange, $n=19$), and severe (red, $n=33$) patients. (f) Peak individual serum levels of gp130 and IL-6R α are shown as linear correlations with the sum of days each patient spent in moderate or severe S/F status, termed “non-mild days”. Maximal disease severity indicated by color (moderate [orange, $n=20$]; severe [red, $n=19$], or deceased [black, $n=3$]). (a, b) Significance was determined by two-side Mann Whitney Wilcoxon test and p-values are indicated by asterisks (*, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$, ****, $p \leq 0.0001$). (c-f) Shaded areas represent 95% confidence interval.

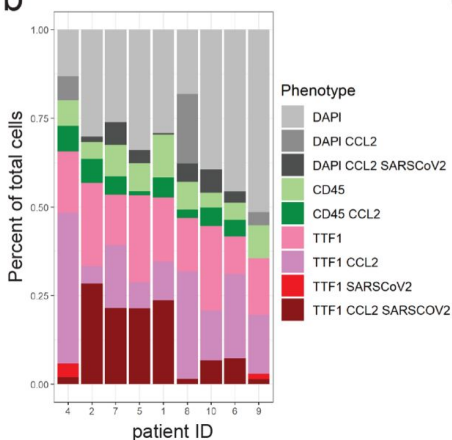

Supplemental Fig 6: IL-6 and CCL2 are not predominantly produced by macrophages. (a-d) RNA was extracted from PBMCs from 6 patients who had either high or low levels of serum IL-6. Serum protein levels of IL-6 (a) and CCL-2 (b) in this cohort are shown. Expression of IL-6 (c) and CCL2 (d) mRNA from PBMCs was evaluated by RT-PCR. Error bars in (a-d) show mean + SD. Significance was determined by two-side Mann Whitney test and p-values are indicated by asterisks (*, $p \leq 0.05$; **, $p \leq 0.01$). (e-f) Representative image showing IL-6 expression outside of CD68+ (e) and CD163+ (f) macrophages. Multispectral images were acquired at 40x magnification. Multiplex immunofluorescence staining was performed for IL-6 RNA (red) and CD68 (panel e, green) or CD168 (panel f, green), and nuclear DAPI counterstain (blue).
