ABSTRACT

One of the health aspects in the development process is the development of human resource potential (HR). What plays a role in this potential of human resources is good nutritional status from an early age. In addition to these factors, the quality of human resource formation is also influenced by the environment that shapes human character, namely the socio-cultural environment (Soekirman, 2005). One of the cultural interactions that affect nutritional status as a condition for the formation of quality human resources is the practice of breastfeeding and the practice of early breastfeeding initiation (IMD). There have been many previous studies that have written that there are still many mothers who do not practice IMD, where one of the reasons mentioned is the belief that the first milk that comes out is dirty and unhealthy, so it is not suitable to be given to babies (Roesli, 2008). The purpose of this literature study is to determine the influence of culture in the practice of early breastfeeding initiation.

The articles used in the literature review were obtained through databases of international journal providers such as Proquest, Google Scholar and Science Direct. The journal was taken from 2019 to 2021. Researchers used keywords, namely transcultural nursing, breastfeeding (according to MESH/Medical Subject Heading) and 20 articles were analyzed using PRISMA diagrams. The analysis found that most mothers did not practice early breastfeeding because of certain beliefs about early breastfeeding, such as early breastfeeding was not as good as exclusive breastfeeding, dirty early breast milk, unhealthy early breastfeeding given to babies and the habit of mothers who immediately gave additional food immediately after the baby is born.

Keywords: early breastfeeding initiation practice, cultural perspective, systematic review.

INTRODUCTION

The health aspect in the development process one of them is the development of human resource potential. What plays a role in the potential of human resources is good nutritional status from an early age. In addition to these factors, the quality of human resource formation is also influenced by the environment that

shapes human character. Socio-cultural environment (Soekirman, 2005). This environment can help shape the interactions, communication, values, norms and cultural ethics that are long established that are passed down through generations. One of the cultural interactions that affect

nutritional status as a condition of the establishment of human resource quality is the practice of breastfeeding and the practice of early breastfeeding initiation (EBI). Many previous studies have written that there are still many mothers who do not practice EBI, which is one of the causes mentioned is the belief that the milk that first comes out is unhealthy for the baby so it is not worth giving to the baby (Roesli, 2008).

EBI coverage in Buleleng Regency in 2020 only reached 32% even though the target in Indonesia is 80%. This coverage is still very far below the target in Indonesia, so efforts to improve EBI practices are the focus of local health policies that must be considered by every childbirth helper (Dinkes Bali Province, 2020).

Culture and tradition are inseparable in human life. According to Leininger (2002) humans tend to maintain their habits wherever they are. Leininger divided the socio-cultural dimensions of seven factors: 1) Technological factors; 2) Religious factors and philosophy of life; 3) Social factors and family attachments; 4) Cultural values and way of life; 5) Applicable policy and regulatory factors; 6) Economic factors; and 7) Educational factors. These factors according to Leininger can affect health.

In the practice of EBI, EBI behavior is strongly influenced by the hereditary tradition inherited by the mother from her family, each mother tends to apply different EBI behaviors. So in this condition, the behavior of EBI carried out by the mother can be said to be a cultural practice because it shows different behaviors. Some research reveals that cultural practices that occur in the

community can inhibit the practice of EBI, but there are also those who support the practice of EBI. Like research conducted by Mayangsari, R (2019) who wrote IMD can not be separated from the prevailing cultural influence in society. In Kendari City there are still mothers who believe and believe that colostrum is dirty breast milk and giving honey at an early age is good for the health of newborns. Some people think that formula milk is better than breast milk. Ningsih Research, RR (2021) writes that 49,5% of mothers in Posyandu work area of Samarinda New Hope Health Center, the practice of early breastfeeding initiation carried out is strongly influenced by the local culture, where breast milk that comes out first must be discarded because it is dirty breast milk. While Wagner, S (2019) writes that mothers who have experience doing EBI practice will affect the duration of subsequent breastfeeding.

Traditions and beliefs develop for generations which will cause people's behavior to lead to the traditions that have been believed. Myths that develop in society in general can affect the practice of EBI, such as the myth that colostrum is stale milk, early delivery of solid food/ honey will be good for the growth and development of children, parenting patterns that develop in the community and supported by low maternal and family knowledge will cause mothers to practice EBI such as beliefs or traditions that are believed to be true for generations. Socio-cultural beliefs come from what has been seen before. Trust that has been formed will be the basis of a person's knowledge and behavior..

METHOD

Articles used in literature reviews are obtained through the database of international journal providers such as Proquest, Google Scholar and Science Direct. Journals are taken from 2019 to 2021. Researchers used keywords namely transcultural nursing, breastfeeding (according to MESH / Medical Subject Heading) and selected full text. There were 895 findings, then narrowed by monitoring duplication

and found 391 findings. Then there are restrictions on articles that are less relevant and found 402 articles, then narrowed down again with restrictions on full text articles that can be accessed found as many as 102 articles. Based on the determination of inclusion criteria obtained 20 appropriate articles. The process of searching for articles in the journal, described in the PRISMA chart flow as follows:

RESULTS AND DISCUSSION

Early Breastfeeding Initiation (EBI) is a process of allowing the baby with his own instinct to breastfeed immediately within the first hour after birth, along with contact between the baby's skin and the mother's skin, until the baby suckles himself (Ministry of Health, 2008). The way babies do EBI is called The Best Crawl or crawling looking for breasts (Maryunani, 2012). In foreign terms EBI is called early initiation breastfeeding. When a healthy baby is placed on the mother's stomach or chest immediately after birth and skin to skin contact is an amazing show, the baby will react by the stimulation of the mother's touch, the baby will move over the mother's abdomen to look for the mother's breasts (Roesli, 2012). The many benefits obtained by babies through the EBI process, causing the World Health Organization (WHO) to recommend EBI be implemented as part of the labor process, and in Indonesia EBI has begun to be socialized since August 2007 (Kemenkes RI, 2012).

Pitaloka research (2017) in Yunitasari, E, et al (2021) states that public figures and religious figures influence the behavior of mothers in breastfeeding their babies. People believe the tradition and culture of combining milk with water or additional food will accelerate the growth of the baby. While Karnasih's research, IGA (2021) mentions one of the factors postpartum mothers in East Java do not breastfeed their babies is due to socio-cultural related factors adopted by mothers and their families. Mishbahatul (2017) in his research conducted in Madura, found the fact that the practice of

breastfeeding companion feeding before the baby is 6 months old because of the belief that babies given breast milk companion food earlier will grow better and sleep better. Based on some of these researches, culture and tradition are one of the factors that affect breastfeeding in infants in Indonesia.

Early breastfeeding initiation policy has been socialized in Indonesia since August 2007 (Roesli, 2012). The World Health Organization (WHO) has recommended to all infants to get colostrum on the first and second day to fight various infections and get exclusive breast milk for 6 months (Kemenkes, 2012).

Research conducted by Susanto, T, et al. (2021) in Jember Regency, East Java found that many mothers do not practice early breastfeeding initiation and exclusive breastfeeding due to ignorance, unwillingness and incompetence that are influenced by the lack of family support. Habits in the family that give up the entire business of breastfeeding to the mother without optimal support, turned out to be an obstacle to the success of breastfeeding in the mother. Mishbahatul, E, et al. (2019) revealed the tradition and belief in families in Madura that the earlier giving solid food to babies will accelerate the baby's weight gain, this belief is certainly not in line with the theory regarding the practice of early breastfeeding initiation.

As research conducted by Akter, F, et al. (2019); Bolton, KA, et al. (2019); Camier, A, et al. (2021); Dowle, KM, et al (2021) the immigrant population is actually more likely to initiate early breastfeeding that continues in

exclusive breastfeeding compared to natives in the United States because of the belief that milk is rich in benefits when compared to other types of food for infants. While the study conducted by Mavisoa, MK, et al. (2021) in Papua New Guinea, not all primipara mothers can practice early breastfeeding initiation even though this program has been implemented as part of the labor process. This is due to the imbalance of gender roles as a cultural heritage in Papua New Guinea, where fathers play an important role in decision-making in the family. While research conducted by Aakre, I, et al. (2019); Goes, FGB, et al. (2019); Cotelo, MdCS, et al. (2019); Yugistyowati, A, et al. (2020) in Kulon Progo Regency actually found a cultural practice that supports the practice of breastfeeding in infants. Mothers and families believe that the more often the baby is breastfed, the baby will grow well and rarely get sick.

Research conducted by Abuhammad, S, et al. (2021) in Jordan found that the culture of mother and baby attachment during childbirth helps increase the production of oxytocin that can affect milk production, so health workers are advised to pay attention to this aspect in the provision of care to the mother by doing follow-up to the mother and baby after birth. While research conducted by Potts, KS, et al. (2021) on breastfeeding mothers in Ethiopia found a cultural relationship of eating in nursing mothers that can affect the nutritional status of infants, it is necessary to approach socio-culturally to change eating habits in the family so that the nutritional needs of babies breastfed by their mothers can be met through the adequacy of feeding in the mother.

Cultural aspects that are inherited for generations in the family, need to get special attention in providing nursing care to post partum mothers. Karnasih, IGA. (2021) through her research found that the application of a culture-based nursing model (Leininger) can help increase maternal knowledge about the importance of early breastfeeding initiation practices, because mothers have the full support of the family and cultural aspects brought by mothers and families are not used as obstacles in breastfeeding practices, but instead be used as boosters of maternal and family beliefs so that breastfeeding practices can be done exclusively.

This research is also in line with research conducted by Edwards, R, et al. (2021); Naragale, YM, et al. (2020); Naeini, MA, et al. (2021); Yunitasari, E, et al. (2020) who found that a culture-based approach turned out to be very good for mothers and families to help mothers carry out optimal breastfeeding practices, because the beliefs that exist in mothers are strengthened with the full support of the family.

CONCLUSION

As a government commitment to EBI practices, the Indonesian government supports WHO and UNICEF policies recommending EBI as a life-saving measure, as EBI can save 22% of babies who die before the age of one month. Breastfeeding for the first hour of life that begins with skin contact between mother and baby is declared a global indicator. EBI is a government program so that it is expected that all health workers at all levels of health services can socialize and implement the program so that it is expected that quality Indonesian human resources will be achieved.

As a nurse, in providing care to mothers during breastfeeding, the ability to recognize the cultural perspective that the mother believes to be a tradition that is believed to be true in the practice of breastfeeding needs attention. By knowing the cultural perspective that the mother believes in the practice of breastfeeding, nurses can use culture-based communication strategies to mediate these beliefs so that mothers and families do not feel disturbed in the act of denial to tradition, but the practice of breastfeeding can be implemented in accordance with the recommendations that have been set.
