

Supplementary Results

The *SLC35A2* gene has been previously associated with mild MCD or FCD type 1^{1,2} but was more recently confirmed as a genetic marker for the MOGHE phenotype.^{3–5} We originally identified four FCD 1a or mMCD samples with *SLC35A2* variants. However, upon in-depth review of histopathological imaging, we determined that the pathological phenotypes of these samples more closely matched MOGHE and reclassified them accordingly. Thus, we detected alterations in *SLC35A2* exclusively in MOGHE samples. Accordingly, we observed a strong association between *SLC35A2* and MOGHE, with 47.1% (16/35) of MOGHE samples carrying a variant in *SLC35A2*.

As expected, alterations in *FGFR1* were exclusively identified in DNET (29%, 7/24), with multiple alterations identified in the majority of cases (71%, 5/7 *FGFR1*-DNET).^{6,7} Variants in *BRAF* were strongly associated with ganglioglioma⁸, with 77.6% (52/67) of detected *BRAF* alterations occurring in ganglioglioma and 57.5% (46/80) of ganglioma carrying at least one alteration in *BRAF*. Of these, the majority (40/46, 87%) carried the *BRAFV600E* variant. Furthermore, *BRAFV600E* was detected in all three pleomorphic xanthoastrocytoma⁷ samples in our cohort. Of note, we observed six ganglioglioma with both a somatic *BRAF* SNV and a somatic duplication covering the *BRAF* gene (7.5%), one sample with two separate somatic duplications covering *BRAF*, and one sample with two different SNV in *BRAF* (V600E and A764V).

Our gene enrichment analysis revealed a strong association between LEAT and *PTPN11* (Figure 3). Our somatic variant gene discovery also revealed novel associations between epileptogenic brain lesions and two different RAS genes, *NRAS* and *KRAS*. Alterations in *NRAS* showed a strong association with polymicrogyria (PMG) and were exclusively detected in 17% of PMG (2/12). We detected a singular somatic *KRAS* SNV in a cancer driving site in a case of meningioangiomatosis (50%, 1/2), a lesion typically associated with the germline neurofibromatosis 2, but not somatic variants in *NF2*.^{9,10} To the best of our knowledge, we are the first to report an association between RAS genes and epileptogenic lesions. Lastly, we identified an association between somatic alterations in *NF1* and epileptogenic brain lesions. We detected nine *NF1* alterations across seven LEAT, which included two ganglioglioma, two DNET, and three gliomas (Fig 3A). Among these, we identified DNET sample carrying two distinct somatic *NF1* SNV (a splicing variant and a stopgain) and a pilocytic astrocytoma carrying a somatic *NF1* PTV and a somatic CNN-LOH covering *NF1*. We also identified an additional seven *NF1* alterations across five MCD, which

included four FCD II and a single PMG (Fig 3A). From these, we only detected more than one variant in the PMG, which carried three distinct *NFI* alterations (T30K, G26X, and a somatic CNN-LOH covering *NFI*). Our results expand the spectrum of epileptogenic brain lesions associated to variants in the canonical RAS-RAF-MAPK pathway and serve as a foundation for untangling the role of this pathway in lesional epilepsies.

Supplementary Table I: Top hits from gene enrichment analysis

| Gene | Synonymous variants | Missense variants | Nonsense variants | Splice variants | Insertions/deletions | P _{global} (unadjusted) | Q _{global} |
