

Supplementary information

Community factors and excess mortality in the COVID-19 pandemic in England, Italy and Sweden.

Supplementary Section 1. Annual population estimates for England

Annual population was from the Office for National Statistics (ONS) mid-year (June) population estimates by age and sex MSOAs in England, 2015 to 2019. Mid-year population estimates for 2020 at MSOA level were unavailable at the time of writing, 2020 MSOA populations were estimated by distributing 2020 local authority district population estimates (released by ONS 25 June 2021)(1) according to MSOA shares in 2019. However, since the 2020 local authority district populations are mid-year estimates, the population denominators will be affected by the excess mortality during the first wave of the COVID-19 pandemic. To assess this effect we compared the ONS mid-year population estimates to a linear regression of the age stratified populations (2015-2019). The ONS mid-year population estimates take account of births and deaths, but also immigration, emigration and changes due to the demographics of the country(1) which is not the case for a simple linear regression. The population pyramid for England(2) shows that there are likely to be uniform changes in the 80+ age group, but non-uniform changes in the 40-59, 60-69, 70-79 age groups, and this is reflected in the comparison between the linear regression estimates against the ONS mid-year estimates (supplementary figure 1). The 80+ population age groups (M & F) linear regression estimates exceed the ONS mid-year estimates. We assert that this is due to the effect of the first wave of the pandemic where the majority of the COVID-19 deaths were in the 80+ age group(3). Consequently, for our 2020 population denominators we used the ONS mid-year estimates for the 40-59, 60-69, 70-79 age groups, and the linear regression estimates for the 80+ age group.

This issue is of little concern for Sweden, however: In 2020, considering the Swedish population aged 80+, there was < 5,00 excess deaths in relation to the reference period (in total, 58,906 persons aged 80+ died in 2020), which implies that <1% of the total 80+ denominator (80+ population size in 2020: ~540,000) could add to the overall error of the “pandemic year”-denominators (this error should otherwise be analogous to the errors in the denominators for each reference year). Hence, no adjustments of the denominator data were made for Sweden.

Supplementary Fig. 1. Population trends and estimates for England stratified by age and sex showing the comparison between 2015-2019 linear regression and the ONS 2020 mid-year population estimates.

Supplementary Section 2. Details of statistical methods

For the first stage model, we assumed that the number of deaths y_{itk} for the i -th area ($i=1, \dots, 6,791$ for England; $1, \dots, 7,900$ for Italy; $1, \dots, 5,985$ for Sweden), the t -th year ($t=2015, \dots, 2019$) of the comparison period and k -th age group ($k=40-59, 60-69, 70-79, 80+$) is modelled as a Poisson distribution:

$$y_{itk} \sim \text{Poisson}(\lambda_{ikt1} \text{Pop}_{itk})$$

where the log-transformed death rates are modelled as fixed and random effects:

$$\log(\lambda_{ikt1}) = \alpha_0 + \beta_{0k} + b_{0i} + \gamma_t. \quad (1)$$

In (1) α_0 is the common intercept which represents the overall mortality rate, while β_{0k} is the age fixed effect for the k -th age group. To account for the multiple years in the comparison group, γ_t provides a year-specific Gaussian random effect. Area-level effect b_0 are modelled as a combination of a conditional autoregressive structure (u_{0i}), to capture local dependency and independent and identically distributed Gaussian random effects (v_{0i}) to account for the similarities of all the areas in the study region (i.e. each country):

$$b_{0i} = \frac{1}{\sqrt{\tau_b}} (\sqrt{1-\varphi} v_{0i} + \sqrt{\varphi} u_{0i}).$$

The model has a precision parameter (τ_b), while φ represents the weight of the spatially structured component (4). This model provides both local and global smoothing on the underlying death rate λ_{ikt1} .

We obtained the posterior distributions of the death rates in each area, age group and year, λ_{ikt1} ; we then averaged over the 5 years of the comparison period to obtain λ_{ik1} , the expected death rate for the i -th area and k -th age group during the study period under the alternative scenario that the pandemic did not take place.

In the second stage model we estimated the ratio between death rates in the study period and the death rates we would have expected had there been no pandemic, using data for the comparison period. For the number of deaths in the i -th area and k -th age group in the study period, we specified the following model:

$$y_{i,2020,k} \sim \text{Poisson}(\rho_{ik} \cdot \lambda_{ik1} \cdot \text{Pop}_{i,2020,k})$$

where ρ_{ik} represents the age-specific ratio between death rates in the study period and the comparison period (λ_{ik1}).

We modelled the ratio ρ_{ik} in a similar way to stage one using terms to account for both space and age:

$$\log(\rho_{ik}) = \alpha_1 + \beta_{1k} + b_{1i}. \quad (2)$$

Covariates were incorporated into this second stage log-linear model to evaluate their effect on the mortality rate ratio. For univariable effects in (2) we added the term δX_i where X_i is the category of the variable in the i -th area and δ is the associated effect. Similarly for the full multivariable model evaluating the joint effect of all variables we added $\sum_{n=1}^6 \sum_{j=2}^5 \delta_{nj} X_{inj}$ with $n=1, \dots, 6$ covariates and $j=2, \dots, 5$ categories, as the first category is the reference one.

We obtained the posterior distribution of the estimated number of deaths across ages for the study period, calculated as $\hat{y}_{i,2020} = \sum_k \lambda_{ik1} \times \rho_{ik} \times Pop_{i,2020,k}$, and subtracted the corresponding number for 2020 using the rates for 2015-2019, calculated as $\hat{y}_{i,2015-2019} = \sum_k \lambda_{ik1,2015-2019} \times Pop_{i,2020,k}$ where the samples for $\lambda_{ik1,2015-2019}$ are drawn in equal proportions from each of the 5 years of the comparison period allowing the uncertainty to be fully represented. This difference was then divided by the 2020 population over 40 years old in that area and multiplied by 100,000.

Supplementary Section 3. Results

Supplementary Table 1. Characteristics of the 6,791 Middle Super Output Areas in England.

	Mean	Median	Range	Inter-quartile range
Population*	8,288	7,985	2,224 – 26,513	6,831 – 9,320

NO₂ – nitrogen dioxide; PM_{2.5} – particulate matter ≤ 2.5 μm diameter.

Supplementary Fig. 2. Choropleth maps of MSOAs in England showing categories of covariates. Note ‘workplace visits’ data were not available at MSOA resolution.

Supplementary Fig. 3. Choropleth maps of municipalities in Italy showing categories of covariates. Note ‘workplace visits’ data were not available at municipality resolution.

Supplementary Fig. 4. Choropleth maps of DeSOs in Sweden showing categories of covariates. Note ‘workplace visits’ data were not available at DeSO resolution.

Supplementary Table 7. Excess death rates, percent increase in mortality and posterior probabilities for Middle Layer Super Output Areas in England.

	Mean	Median	Range	Inter-quartile range
Excess death rate (M), per 100,000 males over 40	316	291	-362 – 1,383	173 - 441
Excess death rate (F), per 100,000 females over 40	230	205	-403 – 1,840	102 - 330
Percent increase in mortality (M)	17.8	16.5	-16.3 – 82.9	9.90 – 24.3
Percent increase in mortality (F)	14.0	13.3	-18.3 – 62.7	6.84 – 20.4
Posterior probability that excess rate is greater than zero (M)	0.881	0.946	0.024 – 1.00	0.834 – 0.990
Posterior probability that excess rate is greater than zero (F)	0.813	0.878	0.023 – 1.00	0.722 – 0.961

M – male; F – female.

Supplementary Table 8. Excess death rates, percent increase in mortality and posterior probabilities for municipalities in Italy.

	Mean	Median	Range	Inter-quartile range
Excess death rate (M), per 100,000 males over 40	307	273	-353 – 1,575	127 - 436
Excess death rate (F), per 100,000 females over 40	278	249	-382 – 2,332	108 - 402
Percent increase in mortality (M)	15.5	13.8	-19.6 – 79.2	6.26 – 21.5
Percent increase in mortality (F)	14.0	13.0	-24.3 – 59.6	5.66 – 20.8
Posterior probability that excess rate is greater than zero (M)	0.852	0.940	0.0007 – 1.00	0.761 – 0.993
Posterior probability that excess rate is greater than zero (F)	0.831	0.914	0.0000 – 1.00	0.729 – 0.987

M – male; F – female.

Supplementary Table 9. Excess death rates, percent increase in mortality and posterior probabilities for DeSOs in Sweden.

	Mean	Median	Range	Inter-quartile range
Excess death rate (M), per 100,000 males over 40	156	94.9	-986 – 3,042	-44.1 – 278.8
Excess death rate (F), per 100,000 females over 40	95.5	24.2	-1,604 – 3,507	-87.6 - 178
Percent increase in mortality (M)	9.19	7.07	-28.8 - 102	-2.24 – 18.3
Percent increase in mortality (F)	4.98	2.84	-32.6 - 148	-6.09 – 13.5
Posterior probability that excess rate is greater than zero (M)	0.588	0.592	0.0365 – 1.00	0.416 – 0.766
Posterior probability that excess rate is greater than zero (F)	0.518	0.504	0.0155 – 1.00	0.348 – 0.683

M – male; F – female.
