

Supplementary material

2 Figure S1. Changes in the rate of healthcare worker mobility and patient contact on non COVID-19 wards in
 3 the Tower building at University College London Hospital. The rate of healthcare worker mobility was
 4 measured in terms of the daily number of door events per healthcare worker, and the rate of patient contact
 5 was measured in terms of the daily number of logged patient contacts per patient. Non COVID-19 wards were
 6 identified as those that had $\leq 15\%$ of all COVID-19 patients (grey polygon) during the observation period. For
 7 each of the two measures, the normalized difference (N) to the average daily rates during the pre-pandemic
 8 (red/yellow points, representing percentage change) was calculated, and a smooth was applied using a seven
 9 day rolling average (red/yellow line). The black dotted line represents 0% change compared to the average in
 10 the pre-pandemic period. Data for October 2020 was not available.
