2	
3	Semiology during video-EEG and OPM recording – Patient #7
4	During the video-EEG recordings, two types of seizure were recorded:
5	Type 1
6	Patient opens eyes, sits up if he was in supine position. For seizures that start when he
7	is awake: he tries to say that he has a seizure, but does not finish sentence.
8	Looks frightened, eyes wide-open, face contorted. Left eye a bit more closed than right
9	eye. Generalized increased tone for seconds (e.g. visible by raising of the shoulders),
10	followed by hyperkinetic seizure with kicking, rocking movements with body,
11	changing between sitting and lying down. Early in the seizure there is (if right-side is
12	visible) a dystonia of the right hand. Large amplitude circular repetitive movement of
13	the right arm. Eventually the movements stop, following which oromandibulaire
14	automatisms (smacking/chewing), sometimes with right-sided manual automatisms,
15	unforced slow head deviation to the left. Sometimes some noises/audible breathing.
16	Impaired awareness. Post-ictally he speaks little and slowly, which may be aphasia, but
17	is difficult to differentiate from a post-ictal state. During some seizures with initial
18	hypermotor semiology as described above, this is not followed by temporal semiology,
19	and patient also responds earlier when he is tested.
20	

21 *Type 2*

Oromandibulaire automatisms, with some salivation, impaired awareness. Sometimes more subtle hyperkinetic semiology (subtle movements of legs/arms/trunk), generalized increased tone, blinking. Post-ictal possibly aphasia, but also difficult to differentiate from a post-ictal state (does not name, or very slow). On EEG these seizures have a right temporal onset and right temporal propagation pattern.

27

28 During the OPM recordings, the following semiology was observed:

Starts with eyes closed. Brief (~1 sec) blinking, then moves head forwards and back. Crosses arms in front of chest, looks up, frightened, with left eye closed and right eye wide open. Hypermobility, kicking, rocking movements with body and swinging left arm. Generalized increased muscle tone, unforced slow head deviation towards left, face contorted with mouth wide-open, following which some oromandibulaire automatisms (chewing). Early in the seizure there is a dystonia of the right hand.
Eventually fewer movements, and leaning backward towards the left. Then sits straight
and removes bandage from left arm and wipes nose with left arm. Impaired awareness.
Remains restless for several minutes: head movements, intermitted eyes-open, fiddling
with chin-strap, oromandibulaire automatisms, wipes nose with left arm.

39

40 Conclusions

The semiology observed during the OPM recording is in agreement with the semiology observed for seizures of Type 1 during video-EEG. sEEG has shown that these have a left temporal onset and propagation, or right frontal/temporal onset with rapid propagation to left temporal, with a further left temporal propagation (see also Table 1).

46 Automatic identification of interictal epileptiform discharges

Interictal epileptiform discharges (IEDs) were automatically identified using a matlab-47 implementation of the BrainSpike algorithm in BrainWave (version 0.9.162.4; 48 developed by C.J.S.; available from https://home.kpn.nl/stam7883/). The algorithm 49 detects spikes in sliding 1-sec windows, using steps of half a second. The windowed-50 data in a channel is converted to Z-scores, based on the mean and standard deviation 51 52 for that window. If an event with a maximum Z-score exceeds a threshold within the middle 500 msec of the window (a threshold of 4, 3.5, 3.5, and 4.5 was used for patient 53 #1, #3, #4, and #6, respectively), and if the event has a minimum and maximum duration 54 (defined as the time between zero-crossings) of 20 and 200 msec, respectively, then it 55 is marked as a potential IED. The algorithm was re-run on negated data in order to also 56 identify 'negative' IEDs, and the IED with the maximum Z-score within a window, and 57 across channels, was kept. Thus, a single Z-value was obtained for each IED, which 58 was used as a proxy for the IED's SNR. 59 In order to reduce the number of false positives, the algorithm was run on only 60

- a selection of channels. The channel-selection was based on the field maps of the IEDs
- 62 that had already been identified on the basis of a visual analysis of the data.

63 Supplemental Figures

65 66 dBy/dz, and Bz & dBz/dz) was used in order to reduce the number of coils needed to minimise the field 67 68 in all 3 directions, as well as the (linear) field gradients in the z-direction by a co-optimised coil design 69 process (Holmes et al., 2019). Red and blue coloured wirepaths denote regions of opposing current flow. 70 For the Bx & dBx/dz, By & dBy/dz coils driving the two planes with equal and opposite input currents 71 generates a uniform magnetic field, driving the two planes with equal and same-signed currents generates 72 a linear magnetic field gradient. For the Bz & dBz/dz coil, driving the two planes with equal and same-73 signed input currents generates a uniform magnetic field, driving the two planes with equal and opposite 74 currents generates a linear magnetic field gradient. Two coils were added to allow nulling of the dBy/dy 75 and dBx/dy gradients, in this case there is no shared symmetry which can be exploited so the windings 76 of each plane were connected in anti-series. Grooves for each coil wirepath were routed into Forex PVC 77 (polyvinylchloride) planes of 1.8 x 1.8 m². Enamelled copper wire of diameter 0.56mm was pressed into 78 the grooves and fixed in place with tape at strategic positions. A front panel was added to prevent galvanic 79 contact between the patients and the coils, and the stacked planes were placed inside a PVC frame (see 80 lower-right sub-figure). The balanced coil pairs were connected individually, and the dBy/dy and dBx/dy 81 coils in anti-series, to low-noise, 4 V, coil drivers (OuSpin Inc). Using this setup, the coils can generate 82 uniform fields or field gradients within a 40 x 40 x 40 cm³ volume between the centre of the panels. Bi-83 planar coil systems similar to those described here are commercially available (e.g. from Cerca Magnetics 84 Limited, Nottingham, UK).

Figure S2: sEEG setup and OPM-placement for patient #3. Panels **a)** and **b)** show the depthelectrodes (green) with respect to the brain and scalp, respectively. The OPMs were placed over the right superior temporal/parietal lobe (electrode with label 'MEG1R') as this is where seizures started in the sEEG recordings, and where previous clinical MEG had localised IEDs. Using the OPM placement as in panel **c)**, the OPM that is indicated with a red rectangle recorded IEDs in the Bz channel. When this OPM

85 86

87

88

89

panel c), the OPM that is indicated with a red rectangle recorded IEDs in the Bz channel. When this OPM
was moved forward (panel d)), IEDs were not visible anymore. Blue arrows indicate the OPMs' sensitive
axes (By and Bz), with By approximately parallel to the head and Bz approximately perpendicular to the
head.

98 Figure S3: Ictal onset for patient #7. Source-reconstructed OPM data for temporal (a) and subcortical 99 (b) channels in the BNA atlas (see (Fan et al., 2016) for nomenclature). Channels from left and right hemisphere are alternated. The grey vertical lines mark 1 second of data, that were filtered between 3 -100 101 48 Hz. Note the increase in fast activity, simultaneously in both hemispheres, after about 9 secs (red 102 vertical line), marking the start of the seizure. This is followed by artefacts due to movement during the 103 seizure. Panel **c** shows a segment of seizure activity, Type 1, from a video-EEG recorded in 2021. Seizure 104 from drowsy state, EEG applied according to the 10-20 system with extra electrodes from the 10-10 105 system (anterior frontal (AF7/8), frontotemporal (FT9/10, FT7/8), temporal (T9/10), centroparietal 106 (CP5/6)). Average montage. The grey vertical lines mark 1 second of data, amplitude 70  $\mu$ V/cm, high and low pass filter of 0.27 Hz and 15.0 Hz, respectively. The seizure starts with attenuation of the 107 108 background pattern (1st blue vertical line from the left), followed with diffuse beta activity (2nd blue 109 vertical line; mainly fronto-temporal), then beta mixed with muscle artefact (although no patient 110 movements were visible yet), followed by large movement artefacts. Note the similarity in temporal 111 evolution in the video-EEG and OPM recording. Panel d shows a segment of seizure activity, Type 1, 112 from an sEEG recording from 2021. Only electrodes involved in the seizure onset are depicted (05INSL: 113 entry: frontal, target: anterior insula. 06HCL: entry: temporal, target: left hippocampus. 07GFL: entry: 114 temporal, target: left fusiform gyrus). Bipolar montage. The grey vertical lines mark 1 second of data,

- amplitude 700 µV/cm, high and low pass filter of 0.27 Hz and 100 Hz, respectively. UEO: unequivocal
- 116 electrographic onset. UCO: unequivocal clinical onset. Seizure onset (1st blue vertical line): 2.5 Hz
- spike-wave complexes on position 6HCL1-3, also visible at 5INSL1-8 and less pronounced at 7GFL1-8,
- followed by irregular high frequency activity and subsequent beta activity with a frequency of ~20 Hz on 06HCL1-3. Seizure propagation (not shown) in consecutive order: left posterior temporal lobe (GFL),
- 120 left anterior cingulate cortex (anterior and dorsal part) and left frontobasal area.

124 Figure S4: Interictal activity for patient #7. Independent IEDs were observed over the left (a) and right 125 (b) temporal lobes, as well as simultaneously over both temporal lobes (b). The first 6 channels were 126 placed over the right hemisphere and the last 6 channels over the left hemisphere; alternating channels show recording in the OPMs' By and Bz direction. Note the ECG artefact on channel 2 and 8, which was 127 128 removed/reduced through beamforming (c). Panel c shows the same segment of data as in panel b, 129 source-reconstructed to the subcortical channels in the BNA atlas. Channels from left and right 130 hemisphere are alternated. The grey vertical lines mark 1 second of data, that were filtered between 3 -131 48 Hz.
