### **S1. Part of the Regional Atmospheric Chemistry Mechanism (RACM) used in this study**

As all inorganic reactions are explicitly included in the OFR mechanism, which is more suitable for the chemistry under GUV, the inorganic part of the RACM mechanism is not used in this study. For simplicity, we generally only include the organic species that are emitted in the case studies in the present work and those that are products of the emitted species in the RACM. Products of a reaction with a yield (stoichiometric coefficient)  $<0.1$  are considered minor and neglected in that reaction. A few reactions (e.g., photolysis of acetic acid (Fig. 1b)) are added to include the chemistry that can occur under UVC irradiation but cannot under UVA and UVB irradiation (only the latter is accounted for by the RACM). Also, as  $\text{NO}_3$  concentration is very low in this study, reactions of organics with  $\text{NO}_3$  are neglected. All organic reactions used in this study are listed in Table S1.

### **S2. Lumping the species in the emission inventory of McDonald et al. into species used in the RACM**

We lump the (indoor fraction of the) species listed in Table S8 of McDonald et al.<sup>1</sup> into the most similar species in the RACM. The mass fractions of the species in McDonald et al.'s emission inventory in the total VOC are assigned to the mass fractions of the corresponding RACM species. The indoor emission fractions of the RACM species are estimated as a rough average of those of the lumped species in the McDonald et al. inventory. The resulting indoor mass fractions of the RACM species are renormalized, and with a total VOC of  $1.7 \text{ mg m}^{-3}$  assumed, the concentrations of individual RACM species can be calculated. The correspondence of the RACM species to those in the McDonald et al. inventory and the estimated indoor emission fractions and normalized mass fractions of the RACM species are shown in Table S2.

### **S3. Indoor air exchange rate for the GUV254 case and UV intensity for the GUV222 fixture**

The GUV254 fixture in this study has a UV intensity of  $\sim 1 \times 10^{14} \text{ photons cm}^{-2} \text{ s}^{-1}$  for the averaged irradiated section area of  $4.5 \text{ m}^2$ , leading to a virus inactivation rate of  $\sim 500 \text{ h}^{-1}$  for the irradiated zone. The air exchange rate (between the irradiated and unirradiated spaces) for the irradiated zone, 240 ACH, is comparable. As the volume of the irradiated space is 15% of the whole room, the effective virus removal rate for the whole room by GUV254 is  $\sim 30 \text{ ACH}$ .

For the 222 nm UV, we assume its intensity to be uniform all over the room. The same effective virus removal rate as in the occupied unirradiated zone for GUV254 corresponds to a UV

intensity of  $3.9 \times 10^{12}$  photons  $\text{cm}^{-2} \text{ s}^{-1}$ , with a UV inactivation rate coefficient of  $1.42 \text{ cm}^2 \text{ mJ}^{-1}$  for SARS-CoV-2 at 222 nm.<sup>2</sup>

#### **S4. Sensitivity GUV cases with high VOC emissions**

These sensitivity cases for GUV254 and GUV222 have x10 indoor VOC emissions as an example of a very polluted indoor space. All other settings for this case are the same as the corresponding GUV254 and GUV222 cases with low ventilation. Compared to the standard low-ventilation GUV cases, the steady-state concentrations of gas-phase organic products and SOA are ~5-10 times higher.  $\text{O}_3$  is lower because of stronger limonene ozonolysis. Relative to a no-UV case with x10 VOC emissions, SOA formation enhancement due to GUV is ~4  $\mu\text{g m}^{-3}$  in the GUV254 sensitivity case. In the GUV222 sensitivity case, GUV-enhanced SOA formation is ~60  $\mu\text{g m}^{-3}$ , largely due to limonene ozonolysis promoted by GUV222-induced  $\text{O}_3$  production.

These SOA enhancements account for similar fractions of total SOA formation as in the standard low-ventilation GUV254 and GUV222 cases.

#### **S5. Sensitivity GUV cases with wildfire smoke in the outdoor air**

These sensitivity cases for GUV254 and GUV222 have a highly polluted outdoor air composition. We assumed that in the outdoor air there is wildfire smoke with an OA concentration of 200  $\mu\text{g m}^{-3}$ , which is an upper limit for wildfire smoke in urban areas in the Western US.<sup>3</sup> The fractions of gas-phase organic species in the total organic carbon are estimated based on the wildfire plume organic species concentrations reported by Heald et al.<sup>4</sup> These species are lumped with the most similar species in the chemical mechanism used in this study. The NO concentration is estimated based on the emission factors reported by Urbanski.<sup>5</sup>

Compared to the base low-ventilation GUV254 and GUV222 cases, all changes in the stable organic product concentrations are within 20%, except for those with high concentrations outdoors, e.g., OA and PAN. The increases in the concentrations of these species are dominantly due to ventilation. At higher ventilation rates, the increases in the indoor concentrations of even more species (e.g., NO and ketones) are dominated by the ventilation.

	Ketones except acetone (molecules cm <sup>-3</sup> )	7.61E+10	7.61E+10	1.00
	Peroxides (molecules cm <sup>-3</sup> )	1.19E+08	1.12E+08	1.07
	Organic nitrates (molecules cm <sup>-3</sup> )	8.99E+08	8.59E+08	1.05
	Alkylperoxys (molecules cm <sup>-3</sup> )	1.96E+08	8.08E+07	2.42
	Acylperoxys (molecules cm <sup>-3</sup> )	2.31E+05	5.61E+04	4.11
	SOA (µg m <sup>-3</sup> )	1.75E-01	1.67E-01	1.05

**Table S4.** Mass yields of secondary organic aerosol produced through several volatile organic compound oxidation pathways.

VOC + oxidant	Mass yield	Source
LIM + O <sub>3</sub>	20%	Estimated based on ref 8
LIM + OH	13%	Ref 1
HC8 + OH	10%	Rough average of yields for corresponding species in the inventory of ref 1
KET + OH	5%	Rough average of yields for corresponding species in the inventory of ref 1
TOL + OH	9%	Ref 1
XYL + OH	4.9%	Ref 1

(c)

(d)

**Figure S1.** Alkyl  $\text{RO}_2$  fate estimated per Peng et al.<sup>9</sup> (a) bimolecular fate and (b) fate including unimolecular isomerization in the low-ventilation GUV254 case, and bimolecular fate in the (c) medium- and (d) high-ventilation GUV254 cases.  $\text{RO}_2$  unimolecular isomerization rate coefficient is assumed to be  $0.1 \text{ s}^{-1}$ , typical for oxygenated VOCs.<sup>10</sup> “ $\text{RO}_2 + \text{RO}_2$ ” denotes the reaction between an alkyl  $\text{RO}_2$  and an acyl  $\text{RO}_2$ , with a rate coefficient assumed to be  $1 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ .<sup>11</sup>
