

Supplementary material:

Understanding the impact of disease and vaccine mechanisms on the importance of optimal vaccine allocation

Isobel R. Abell, James M. McCaw, Christopher M. Baker

S1 Model details

In this section we briefly restate our model and parameter definitions, and we list the default values for each parameter. This is to provide the full model in a single, succinct section. We then provide extra results in Section S2.

We consider the model as defined by Eqs. (2)–(16):

Unvaccinated: (1)

$$\frac{dU_i}{dt} = -\lambda_i(t)U_i(t) \quad (2)$$

$$\frac{dE_{U_i}}{dt} = \lambda_i(t)U_i(t) - \theta E_{U_i}(t) \quad (3)$$

$$\frac{dI_{US_i}}{dt} = \omega_i \theta E_{U_i}(t) - \gamma I_{US_i}(t) \quad (4)$$

$$\frac{dI_{UA_i}}{dt} = (1 - \omega_i) \theta E_{U_i}(t) - \gamma I_{UA_i}(t) \quad (5)$$

$$\frac{dR_{US_i}}{dt} = (1 - \sigma_i) \gamma I_{US_i}(t) \quad (6)$$

$$\frac{dD_{U_i}}{dt} = \sigma_i \gamma I_{US_i}(t) \quad (7)$$

$$\frac{dR_{UA_i}}{dt} = \gamma I_{UA_i}(t) \quad (8)$$

Vaccinated: (9)

$$\frac{dV_i}{dt} = -\alpha_1 \lambda_i(t) V_i(t) \quad (10)$$

$$\frac{dE_{V_i}}{dt} = \alpha_1 \lambda_i(t) V_i(t) - \theta E_{V_i}(t) \quad (11)$$

$$\frac{dI_{VS_i}}{dt} = \alpha_2 \omega_i \theta E_{V_i}(t) - \gamma I_{VS_i}(t) \quad (12)$$

$$\frac{dI_{VA_i}}{dt} = (1 - \alpha_2 \omega_i) \theta E_{V_i}(t) - \gamma I_{VA_i}(t) \quad (13)$$

$$\frac{dR_{VS_i}}{dt} = (1 - \alpha_3 \sigma_i) \gamma I_{VS_i}(t) \quad (14)$$

$$\frac{dD_{V_i}}{dt} = \alpha_3 \sigma_i \gamma I_{VS_i}(t) \quad (15)$$

$$\frac{dR_{VA_i}}{dt} = \gamma I_{VA_i}(t) \quad (16)$$

Force of Infection:

$$\lambda_i = \sum_{j=1}^2 \beta C_{ij} \frac{I_{USj}(t)}{LP_j(t)} + \delta_A \beta C_{ij} \frac{I_{UAj}(t)}{LP_j(t)} + \alpha_4 \left[\beta C_{ij} \frac{I_{VSj}(t)}{LP_j(t)} + \delta_A \beta C_{ij} \frac{I_{VAj}(t)}{LP_j(t)} \right], \quad (17)$$

where $LP_i(t)$ denotes the living population at time t . That is,

$$LP_i(t) = P_i - D_{U_i}(t) - D_{V_i}(t),$$

where P_i is the total population of group i at $t = 0$.

S1.1 Parameter definitions

We firstly define the compartments (X_{jki}) included in our model:

- $X \in \{U, V, E, I, R, D\}$: unvaccinated, vaccinated, exposed, infected, recovered, dead
- $j \in \{U, V\}$: unvaccinated or vaccinated disease progression
- $k \in \{S, A\}$: symptomatic or asymptomatic infection
- $i \in \{1, 2\}$: population group (1: high risk of infection, 2: low risk of infection)

The following parameters are defined to be constant across the population groups:

- $1/\theta = 1$: average time spent exposed
- $1/\gamma = 1$: average time spent infected
- $R_0 = 2$ (unless otherwise stated): reproduction number
- $\delta_A = 0.5$ (unless otherwise stated): reduction in infectivity due to asymptomatic infection

The following parameters are defined as specific to each population group i :

- $\omega_i = 0.5$ (unless otherwise stated): proportion of infected people in group i that experience symptomatic disease
- $\sigma_i = 0.5$ (unless otherwise stated): proportion of symptomatic infecteds in group i that die due to disease
- $P_i = 5000$: initial population size for group i
- $[C_{ij}] = \begin{bmatrix} 2 & 2 \\ 1 & 1 \end{bmatrix}$ (unless otherwise stated): Contact matrix
- $I_{0i} = 50$: Initial infected people in group i (half symptomatic, half asymptomatic)

Finally, the following parameters characterise vaccination in our model:

- Vaccine coverage = 5000 (unless otherwise stated): Number of vaccines available
- $1 - \alpha_i = 0.25$ (unless otherwise stated): effectiveness of vaccine i
- $1 - \alpha_1$: reduction in susceptibility from Vaccine 1

- $1 - \alpha_2$: reduction in proportion of infected cases that experience symptomatic infection from Vaccine 2
- $1 - \alpha_3$: reduction in proportion of symptomatic infecteds that die due to infection from Vaccine 3
- $1 - \alpha_4$: reduction in infectivity from Vaccine 4

S1.2 Implicit Assumptions

In our model formulation, we assume that asymptomatic infection is less infective than symptomatic infection. This reduction in infectivity due to asymptomatic infection is denoted by $1 - \delta_A$. For this work we assume $\delta_A > 0$.

Furthermore, we assume people experiencing asymptomatic infection do not experience severe disease. This is implicitly assumed in our model as asymptomatic infecteds can only transition to a recovered compartment, they cannot die due to disease.

S2 Results

S2.1 Figure 2a details

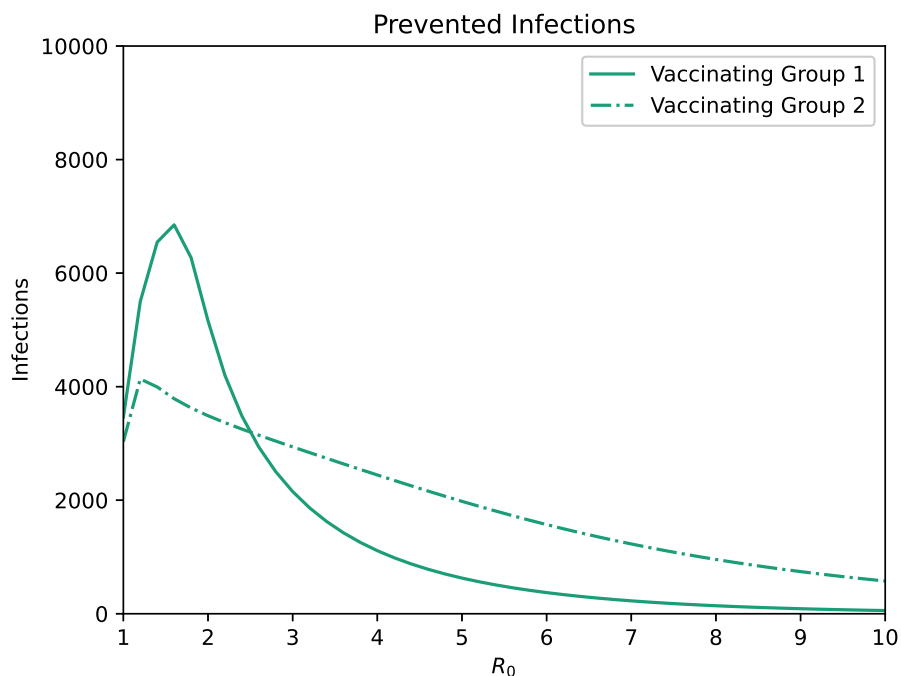

Figure S1: Prevented infections from vaccinating either Group 1 or Group 2. The number of prevented infections is calculated by subtracting the total number of infections with vaccination from the total number of infections without vaccination.

In this section we investigate the intersection point that appears between outcomes of vaccination strategies in Figure 2a. Consider Figure S1, which shows the prevented infections from vaccinating either Group 1 or Group 2. We see that before the intersection point ($R'_0 \sim 2.5$), vaccinating Group 1 prevents the highest number of infections and is hence the optimal strategy. For $R_0 > R'_0$, vaccinating Group 2 becomes the optimal strategy, preventing more deaths than vaccinating Group 1. In Figure 2a, we assume Group 1 is more susceptible to disease than Group 2. As such, for $R_0 < R'_0$, there are few Group 2 infections to begin with, and so the optimal strategy is to vaccinate Group 1 to reduce their many infections. However, as R_0 increases, the number of people infected in Group 1 increases until almost everyone is infected, even if the entire group is vaccinated. We can see this in Figure S1, where as we increase R_0 , we see diminishing returns from vaccinating Group 1, and we see more prevented infections from vaccinating Group 2. The reduced susceptibility of Group 2, compared to Group 1, means that it will take higher R_0 for the entirety of Group 2 to become infected, especially if vaccinated. Hence, we see more prevented infections from vaccinating Group 2 for $R_0 > R'_0$ than from vaccinating Group 1.

S2.2 Extra plots

Here we show how the difference between strategies differs for every combination of vaccine mechanism and allocation objective as we vary specific parameters.

- Varying the contact matrix (Subsection S2.2.1)
- Varying ω_i (Subsection S2.2.2)
- Varying σ_i (Subsection S2.2.3)
- Varying δ_A (Subsection S2.2.4)
- Varying R_0 (Subsection S2.2.5)
- Varying vaccine coverage (Subsection S2.2.6)
- Varying vaccine effectiveness (Subsection S2.2.7)

S2.2.1 Varying the contact matrix
