15	Abstract
16	It is well known that low air temperatures negatively affect the human respiratory system and
1/ 10	can suppress protective mechanisms in airways epithelial cells.
10	In this study, we put forward the hypothesis that the 'compromised airway enithelium' of
20	infected persons can be extremely sensitive to external influences and therefore can be used as an
20	"indicator" and serve to investigate the impact of low air temperatures (as and other external
22	factors) on the respiratory system.
23	
24	Here we supposed that a short-term impact of drop in outdoor temperature on the 'compromised
25	airway epithelium' should lead to increased symptoms and severity of the disease.
26	
27	We have analyzed a short-term impact of the air temperature drop on the worsening of disease in
28	patients with COVID-19 (indicated by bursts of daily hospitalizations), which fell on the main
29	epidemic wave in 2022 associated with SARS-CoV-2 Omicron variant.
30 21	It was found that even a small and/or short-term impact of drop in outdoor daily temperatures
31	can lead to increased symptoms and sevenity of the disease (COVID-19).
32	We have identified 14 characteristic points (days) where the temperature drop was more than 3
34	degrees during the main pandemic wave in 2022. It was shown that each characteristic points
35	clearly associated with characteristic bursts in the number of daily hospitalizations with a time
36	lag of 1-2 days.
37	
38	Thus, it was found that the results of the study can be used in predicting a sudden increase in the
39	number of hospitalizations, which can be used to timely warn clinics and medical hospitals for
40	an increase in the number of seriously ill patients.
41	
42	The findings can be used to improve systems to prevent additional risks connected with impact
43 44	of drop in air temperature on worsening disease in patients and infected people who do not have
++ ∕15	or nave mind or subtre symptoms of the disease – especially during an epidemic or pandemic
ч <i>э</i> 46	wave.

50 Introduction

51 Novel coronavirus disease (COVID-19) is a respiratory infection caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). COVID-19 is a complex disease with 52 53 clinical responses varying from asymptomatic to severe with catastrophic respiratory failure and 54 death (Bridges et al., 2022). The COVID-19 pandemic has resulted in an extraordinary incidence 55 of morbidity and mortality, with 645 million confirmed cases and 6.6 million deaths worldwide 56 (https://covid19.who.int/). 57

- During the natural evolution of the COVID-19 pathogen, dominant variants emerge that account 58 59 for most new infections. The Omicron variant has become the dominant agent of the wave of the 60 COVID-19 pandemic in the beginning of 2022 (Del Rio & Malani, 2022).
- 61

62 It is well known that meteorological factors may influence the incidence of many infectious 63 diseases. It has been suggested that the weather conditions has contributed to spreading the SARS-CoV-2 as a result of the same drivers that contribute to the occurrence of respiratory 64 65 viruses, including seasonal influenza and coronaviruses (see related reviews in (Xie & Zhu, 66 2020; Christophi et al., 2021; Kaplin et al., 2021; Nichols et al., 2021)).

67

68 It was assumed that the dynamics of the COVID-19 pandemic suggests that a high percentage of 69 susceptible people at the beginning of the pandemic means that the effect of the weather was 70 relatively small, but this effect increases in next years as the SARS-CoV-2 becomes endemic and 71 the population's susceptibility to the virus declines (Baker et al., 2020; Nichols et al., 2021).

72

73 The seasonality of respiratory viruses and influenza has been extensively researched and 74 continues to be investigated. Specifically, ambient temperature is considered to be the key 75 climate factor that affects seasonality of respiratory infections. Nevertheless, possibly due to the 76 differences in latitudes and climate regions, the relationship between ambient temperature and 77 respiratory infections was not consistent. Seasonality of respiratory viruses commonly connected 78 with cold seasons in the Northern Hemisphere and wet seasons in tropical countries - these 79 findings provide a simple climate-based model rooted in empirical data that accounts for the 80 diversity of seasonal influenza patterns: "cold-dry" and "humid-rainy" (see related reviews in (Eccles, 2002b; Lofgren et al., 2007; Lipsitch and Viboud, 2009; Tamerius et al., 2013; 81 82 Moriyama et al., 2020; Qi et al., 2022; Li et al., 2022)).

83

84 The seasonality of seasonal coronaviruses has been examined too in many countries across the 85 world and showed seasonal patterns similar to influenza and respiratory syncytial virus (RSV) in 86 temperate climates (see review in (Li et al., 2020; Nichols et al., 2021)). The study by Nichols et al. (2021) has found that seasonal coronavirus infections in England and Wales have a broadly 87 88 similar distribution to influenza A and human bocavirus infections. It has been suggested that 89 forecasting based on weather and climatic conditions (global radiation, relative and/or absolute 90 humidity, air temperature, sunshine (hours per day), dewpoint temperature, precipitation and 91 etc.) might help in preparing health care systems and populations to better protect those most at 92 risk from serious complications from becoming infected (Scafetta, 2020; Nichols et al., 2021).

93

94 It is important to note that while the many studies show associations between some weather 95 parameters and respiratory infections (including COVID-19) it is recognized that the drivers of

96 infection and seasonal epidemics involve combined effects of physical, physiological, social and

97 behavioral elements (Bontempi, 2020; Ishmatov, 2020a; Bontempi and Coccia, 2021; Culqui

98 et al., 2022). Moreover, many of the weather factors auto-correlate to some extent because of

99 their natural relationships in the environment – for example, relative humidity is influenced by

- 100 temperature; temperature can be influenced by sunshine and etc. (Nichols et al., 2021).
- 101

102 Despite a lot of research in this area the seasonality (predictable fluctuation or pattern that recurs 103 or repeats over a one-year period) of COVID-19 is still poorly understood and insufficiently

104 taken into consideration (D'Amico et al., 2022).

105

106 In this study, we put forward the hypothesis of the 'compromised airway epithelium' and the 107 impact of outdoor temperature as the last straw in the disease course.

108

109 The hypothesis is as follows the airway epithelium of an infected person at the first stages of the 110 infection/disease and in the mild and moderate course of the disease (when there are no 111 symptoms or they are insignificant) partially loses its functionality. In such a state, the balance of 112 the functioning of the airway epithelium (as well as its defense mechanisms) can be easily 113 disturbed by different external triggers. This can lead to an even greater weakening of the 114 protective functions in the airway epithelium and, as a result, to the uncontrolled development of the infection.

115 116

117 Thus, here we suppose that even a small and/or short-term impact of drop in outdoor temperature 118 (as well as other factors) on the 'compromised airway epithelium' should lead to increased 119 symptoms and severity of the disease.

120

121 The aim of the study is to find the relationship between the influence of outdoor 122 temperature (as one of the weather factors) and the increased symptoms and the 123 deterioration of the course of diseases during pandemic wave associated with the SARS-124 CoV-2 Omicron strain in 2022.

125

126 Here we based on the mechanistical point of view on how the air temperature could affect the 127 respiratory system and lead to the worsening of the course of the disease and hospitalizations 128 associated with the COVID-19. It is well known that that the respiratory epithelial cells can be 129 critically cooled by inhaled cold/cool air and it can lead to the reduction of antiviral response in 130 the cells, the inhibition of mucociliary clearance (Tyrrell and Parsons, 1960; Salah et al., 1988; Eccles, 2002b; Mourtzoukou and Falagas, 2007; Makinen et al., 2009; Foxman et al., 2015; 131 132 2016; Iwasaki et al., 2017). Foxman et al. (Iwasaki lab) (Foxman et al., 2015; Foxman et al. 133 2016) (Iwasaki et al., 2017) had clearly shown the mechanism of reducing the immune response 134 of cells in the respiratory tract of mice during cooling the cells. The ability of various strains of 135 rhinoviruses replicate more better in the respiratory epithelial cells at 33 °C than at the normal 136 lung temperature of 37 °C. It is also important to note here the mechanism of influence of 137 personal and outdoor temperature exposure during cold and warm seasons on lung function and 138 respiratory symptoms in COPD which was described by Scheerens et al. (2022).

139 140

141 Methods

142 We limited our analyses to the city of Tomsk and the Tomsk agglomeration. Tomsk (56°30'N 143 84°58'E) is a city and the administrative center of Tomsk Oblast in Russia, located on the Tom 144 River. The city's population is 570776 at the end of 2021, with a population density of 1937 145 person/km2. Tomsk has a humid continental climate barely escaping a subarctic classification.

146 The annual average temperature is +1.2 °C. The total annual rainfall is 587 millimeters

147 (URL:https://en.wikipedia.org/wiki/Tomsk (date of access: Jun 1, 2022)).

148

149 We considered the pandemic period from January 1st, 2022, to March 31st, 2022, associated

150 with the SARS-CoV-2 Omicron strain, the dominant agent of the new wave of the COVID-19 151 pandemic in 2022 in the region.

The data of OpenStreetMap® was used, licensed under the Open Data Commons Open Database License (ODbL) by the OpenStreetMap Foundation (OSMF) and the Creative Commons Attribution-ShareAlike 2.0 license (CC BY-SA 2.0).

153

154 The data on measured outdoor temperatures were collected from official reports on weather

status are issued by Regional Directorates of Hydrometeorological Service in Russia:
 http://www.meteorf.ru/about/structure/local/.

157

158 To analyze daily dynamics in the symptom aggravation and disease severity, we used data on

159 daily hospitalizations associated with COVID-19. The statistical data on COVID-19

160 hospitalizations were obtained from open official sources for Tomsk and the Tomsk region

161 (URL: https://gogov.ru/covid-hosp-stats/tms#data (In Russian - date of access: Jun 1, 2022)).

162 Here we hypothesized that short-term fluctuations in outdoor temperature may be associated

163 with an increase in the symptoms of patients with COVID-19 and are associated with the

164 presence of pneumonia at the time of diagnosis of COVID-19 in hospitals (for those cases that 165 fall into official statistics). In our work, we hypothesized that many COVID-19 pneumonia

166 diagnoses are triggered by activity in the preceding hours.

167

Using a control group of patients for the analysis is a difficult task. And we wondered what 168 169 would be the best representative of the population that set the precedents? – The simple answer 170 was the cases themselves. The case-crossover study design is an adaptation of the case-control 171 study, in which cases serve as their own controls, and is well suited to the study of transient risk 172 factors. We used a parameter of hospitalization and pneumonia as a proxy for the severity of 173 COVID-19 symptoms. Although this may be justified on the grounds that the most severe forms 174 of COVID-19 usually lead to pulmonary manifestations on their own (we did not have any direct 175 measures of severity or a confirmed severity index). We have adapted this approach; this is the 176 same approach that has been proposed for the analysis of cases of heart attacks and severe illness 177 by Maclure (1991), this method was also used in a recent study on individual emergency 178 department visits for COVID-19 (Lavigne, et al., 2022).

178 179

180

181 **Results and Discussion**

182 A graph of outdoor temperatures fluctuations by days is shown in Figure 2. The number of

- 183 hospitalizations by days is shown in Figure 3.
- 184

Figure 2 – Outdoor daily temperature in Tomsk

Hospitalization in Tomsk region, people

185

300 250 200 Hospitalization 150 100 50 0 04.04.2022 17.01.2022 24.01.2022 31.01.2022 07.02.2022 14.02.2022 21.02.2022 28.02.2022 07.03.2022 14.03.2022 21.03.2022 28.03.2022 Date Figure 3 – Daily hospitalizations in Tomsk

186

187 The wave of hospitalizations (Fig. 3) from January 20 (wave start) to March 31 (wave end) can 188 be clearly associated with the main pandemic wave, and here we propose to consider this wave 189 as a "main carrier wave" (see below), which depends on the emergence of a new strain and other 190 global factors, including air temperature too.

191

192 From figure 2 it follows that the temperature was always low (below comfortable values for a

193 person – this corresponds to the time of year for this region), which in itself is the main

194 influencing factor. Therefore, here we consider only temperature fluctuations (temperature drop)

as an additional factor that can make some adjustments to the health condition of infected

196 individuals and, as a result, to "wave beats/bursts" that appear on this carrier wave (pandemic

197 wave) in form of frequency modulation. Conventionally, this approach can be compared with

medRxiv preprint doi: https://doi.org/10.1101/2023.01.04.23284173; this version posted January 5, 2023. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in perpetuity.

perpetuity. It is made available under a CC-BY-NC-ND 4.0 International license .

the principle of superposition of waves — when a "ripple" (frequency modulation) is superimposed on a carrier wave.

200

201 As well as in wave dynamics, we initially believe that the potential of secondary bursts

(modulation) has limited values (and we found confirmation of this, see below (table 1)). For
example, if a surge is caused by some factor, then the subsequent factor may affect this surge too
(the principle of superposition of waves), but this influence may not be so pronounced as the first
factor influence was (the factor that acted as an initial trigger).

206

In any case, many factors can act as triggers for wave modulation. Moreover, all the factors can
act in a joint manner and overlap each other. For example, one factor (for example, temperature,
or air humidity, or an air pollutant, or a weather parameter, etc.) triggers a surge in

210 diseases/hospitalization wave, and then another factor appears and maintains this local surge on 211 the main\ carrier wave.

212

At this stage, we have chosen the task of assessing the influence of air temperature as a simple and obvious acting factor. We believe that the effect of temperature should have an obvious and fast effect – and we found evidence for this in the results of the performed analysis (see below).

216

At the first stage, we looked for obvious and strong changes\drops in the daily temperature, and
then compared them with the number of hospitalizations falling on those days, taking into
account a possible time lag of several hours or days.

220

For the initial determination of the time lag, we chose the most characteristic points in the fig.2, where the temperature changed very strongly during one or two days, – that is, where such influence (drop in air temperature) is likely to be the most noticeable (even taking into account the other influencing factors). Since such a "cold" impact can and should affect the state of the "compromised" respiratory system (in accordance with the hypothesis put forward – see above).

In the next step, we compared changes in hospital admissions (fig. 3), which could correspond to the effects of temperature changes. Here, hospitalizations serve as an indicator of the severity of the disease and the deteriorating health of infected individuals. Thus, thanks to this preliminary stage, we found that the time lag is no more than 1-2 days.

Next, we carried out a detailed analysis of each change (drops) in ambient temperatures and
analysis of each spike in the number of daily hospitalizations. The analysis is shown in table 1.

239 Tmean – daily mean temperature, °C;

240 Tmin – daily minimum temperature, °C;

241 Tmax – daily maximum temperature, °C

Tdiff – temperature difference, °C 242

- 243 Diff – difference in daily hospitalizations.
- 244 245

246 Thanks to the obtained analysis, we have identified 14 characteristic points where the 247 temperature drop was more than 3 degrees (\mathbb{N}_{2} 1-3, 5-8, 10-17) (table 1)) – all of them were 248 associated with characteristic bursts in the number of daily hospitalizations with a time lag of 1-2 249 days.

250

251 In 8 characteristic points of those 14 (N_{2} 1-3, 6, 8, 10, 12, 13) the temperature can be 252 characterized as a primary trigger (which acted as the main influencing factor).

253

254 In 6 characteristic points of those 14 (№5, 7, 11, 14-16) the temperature can be characterized as 255 an additional factor (joint influence with other acting factors).

256

257 In total, 17 characteristic surges in the number of daily hospitalizations were identified over the 258 entire period. Three of them $(N_{2}3, 4, 9)$ had no connection with drop in daily temperature (the 259 temperature did not change in these days) and were associated with other factors.

261 The data from the table once again confirmed the initially found value of the time lag of the

262 short-term effect of temperature drops on worsening of disease in infected individuals (indicated

263 by bursts of daily hospitalizations) – it averaged 1-2 days.

264

265 Thus, it was found that each characteristic points where the temperature drop was more than 3 266 degrees can be clearly associated with bursts in the number of daily hospitalizations.

267

268 It is important to note that since the pandemic started, many authors have analyzed the issue of 269 impact of many factors (weather conditions, air pollution and etc.) on COVID-19 incidence, 270 severity, and mortality, and literature linking to this issue has increased exponentially and now 271 hundreds studies show the different results (see related revies in (Kang et al., 2021; Prévost et 272 al., 2021; Liang & Yuan, 2022; Mandal et al., 2022; McClymont & Hu, 2021; Mejdoubi et al., 273 2020; Runkle et al., 2020; To et al., 2021; Tripathi et al., 2022; Xie & Zhu, 2020; Carballo et al., 274 2022; Culqui et al., 2022; Ishmatov, 2022; Kang et al., 2021; Perone, 2022; Taylor et al., 2022)). 275 Most of the studies are statistical and analyze the correlation between various influencing 276 factors. Moreover, many studies use limited datasets and are subject to several confounders, 277 requiring caution when interpreting these results.

278

279 It is worth noting that today there are many studies of the correlation of weather factors and air temperature with COVID-19 in many countries and cities. Most of them agree that air 280 281 temperature affects COVID-19 and authors describe some possible effects of air temperature on 282 COVID-19 disease severity and transmission rates (see related reviews in (Kang et al., 2021; Prévost et al., 2021; Liang & Yuan, 2022; Mandal et al., 2022; McClymont & Hu, 2021; 283 284 Mejdoubi et al., 2020; Runkle et al., 2020; Tripathi et al., 2022).

285

286 Most of the studies are statistical and have large-scale character - entire countries are studied, 287 many variables are described simultaneously, and long periods are examined. Our study is based 288 on a mechanistic approach – we did not just choose a parameter for correlation analysis, but 289 proposed a clear and precise mechanism of how this parameter can affect and what this effect 290 can lead to. Our study can be characterized by strong concretization of the chosen direction of 291 research, - limited to one city (where the population is evenly exposed to the same impacts 292 (conditionally) and one specific pandemic wave (when one strain of the virus prevails)). Perhaps 293 this approach made it possible to discover the relationships and patterns in this study, which, 294 perhaps, would not be so pronounced for large-scale study.

295 296

297 **Future directions and limitations**

298 Obviously, not every external influence can have the same pronounced effect as the effect of the 299 air temperature. Sunlight, precipitation, humidity, wind speed and etc. – these are indicators that 300 are difficult to consider and analyze, since it is now difficult to associate them with effects on the 301 respiratory system, within the framework of a mechanistic approach proposed in this study.

302

303 Here it is important to consider the air humidity (as a main weather parameter). We examined 304 this indicator in detail and came to the conclusion that it is difficult task for a separate analysis 305 and a detailed study of this issue are required.

306

307 On the one hand the absolute humidity (AH) is directly related to air temperature. Relative

308 humidity (RH) is not so clearly related to temperature, but with sudden changes in daily

- 309 temperature, this relationship is direct (especially for continental climates). For example, the
- 310 maximum moisture content possible in air varies with temperature and as a result, the variation
- 311 of ambient temperature can significantly affects the ambient RH.
- 312

313 On the other hand, air humidity should affect the efficiency of heat and mass transfer in the

314 respiratory tract – thereby affecting the cooling efficiency of the airways epithelial cells.

315 Moreover, low RH should affect the effectiveness of mucosal drying and, as a consequence,

316 affect the mucociliary clearance.

317

But in any case, here relative humidity should always be considered together with temperature –
since temperature (as well as humidity) plays a significant role in heat and mass transfer
processes. This aspect (within the impact on COVID-19) need to be investigated in the future
studies.

322

It is important to note that the conception of the effect of "supersaturation in the airways" which was proposed in (Ishmatov, 2019; Ishmatov, 2020b) is most promising here – because it links temperature and RH into one mathematical function. The main sense of the supersaturation in the airways is that this effect depends simultaneously on both temperature and RH of inhaled air. Thus, temperature and RH are the parameters of one simple function (it is the effect of supersaturation) and no longer need to consider the separate influence of humidity or temperature on the human health.

330

Cold, rainy or wet weather can induce supersaturated conditions in the airways. It was shown
that supersaturation can lead to enhanced deposition of inhaled ambient aerosols, infectious
aerosols and air pollutants in the human airways (Ishmatov, 2017a; Ishmatov, 2020b). Xu et al.
(2021) also confirmed this aspect in the study with the help of numerical experiments.

335

Moreover, role of effect of supersaturation in a critical cooling of local areas in the human upper airways was discussed, and this involves cold stress and reducing, as a consequence, the antiviral immune response of the airway epithelial cells. The additional acidification of epithelial lining fluid in the local areas of the respiratory tract was also considered. Such acidic stress may lead to destructive impacts on the respiratory cells and weakening of the defense mechanisms of the airways (Ishmatov, 2017b; Ishmatov, 2020b).

342

According to the above, the supersaturation effect may be used in the future for predictions and analysis of the changing epidemiological situation (the first attempt was made in (Ishmatov, 2017c)). However, these aspects are preliminary and need to be investigated in the future studies.

346

In our opinion, of all potential influencing factors, air pollution fits the mechanistic approach
proposed in this study. Air pollution here suggests the same effect as temperature since it directly
affects the human respiratory system. Research is currently underway in this direction and first
preliminary results was presented in (Ishmatov et al., 2022).

- 351
- 352

353 Conclusion

Many factors influence the pathogenesis and epidemiology of COVID-19. Considering the whole set of influencing factors at the same time can be quite difficult and it is counterproductive now and therefore it is important to identify the all factors and understand how they mechanistically influence COVID-19 and to evaluate the extent of this impact. It is a rigorous element-by-element analysis of each influencing factor that can now give good results. In the end, thanks to a mechanistic approach, in the future we will be able to assemble the whole epidemiological puzzle brick by brick.

361

We believe that it was a good idea to conduct research using the hypothesis of the 'compromised airway epithelium'. The 'compromised airway epithelium' of infected persons can be extremely

364 sensitive to external influences and therefore can serve as a good indicator of the impact on the

medRxiv preprint doi: https://doi.org/10.1101/2023.01.04.23284173; this version posted January 5, 2023. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in perpetuity.

perpetuity. It is made available under a CC-BY-NC-ND 4.0 International license .

respiratory system of external factors. And the time lag of the impacts is rather short (1-2 days), which gives ample opportunities for analyzing and predicting the consequences of such impacts.

367

Also, the idea of using the wave theory, the principle of superpositions and frequency
 modulation, together with the mechanistic approach, looks quite promising in the analysis of
 epidemic waves. But this requires a strictly mathematical approach to the analysis of all

- 371 influencing factors in the future studies.
- 372

373 In this study we have chosen the task of assessing the influence of air temperature on the 374 respiratory system as a simple and obvious acting factor. It was found that even a small and/or 375 short-term impact of drop in outdoor daily temperatures on the 'compromised airway epithelium' 376 lead to increased symptoms and severity of the disease (COVID-19). Changes in the ambient 377 daily temperature are well predicted for days and weeks by modern methods. And this aspect can 378 be used to improve systems to prevent additional risks connected with impact of drop in air 379 temperature on worsening disease in patients and infected people who do not have or have mild 380 or subtle symptoms of the disease – especially during an epidemic or pandemic wave. It was 381 found that the results of the study can be used in predicting a sudden increase in the number of 382 hospitalizations, which can be used to timely warn clinics and medical hospitals for an increase 383 in the number of seriously ill patients. Thus the findings are another brick in the wall and besides 384 the above, they can also be used in preparing health care systems and populations to better 385 protect those most at risk from serious complications from becoming infected, and support 386 timing of interventions to help achieve this.

387388

389 Acknowledgments

We thank the "CityAir" and Pavel Glotov (General director of "CityAir") for providing
measured meteorological data from weather station located in Tomsk.

393The study was supported by a grant of the Russian Science Foundation No 22-27-20111,394https://rscf.ru/project/22-27- 20111/ and funded by the Administration of the Tomsk Region.
