Running Head: Emphysema blood biomarkers

Descriptor: 9.03 COPD: Clinical Phenotypes

Manuscript Word Count: 3,479

AT A GLANCE COMMENTARY (162/200 words)

Scientific Knowledge on the Subject:

Differential gene expression and protein analyses have uncovered some of the molecular underpinnings of emphysema. However, no studies have assessed alternative splicing mechanisms and analyzed proteomic data from recently developed high-throughput panels. In addition, although emphysema has been associated with low body mass index (BMI), it is still unclear how BMI affects the transcriptome and proteome of the disease. Finally, the effectiveness of multi-omic biomarkers in determining the severity of emphysema has not yet been investigated.

What This Study Adds to the Field:

We performed whole-blood genome-wide RNA sequencing and plasma SomaScan proteomic analyses in the large and well-phenotyped COPDGene study. In addition to confirming earlier findings, our differential gene expression, alternative splicing, and protein analyses identified novel biomarkers and pathways of chest CT-quantified emphysema. Our mediation analysis detected varying degrees of transcriptomic and proteomic mediation due

to BMI. Our supervised machine learning modeling demonstrated the utility of incorporating multi-omics data in enhancing the prediction of emphysema.

Keywords: Emphysema; Biomarkers; Transcriptomics; Proteomics; Prediction

This article has an online data supplement, which is accessible from this issue's table of content online at www.atjsjournals.org

1 **ABSTRACT**

2

3 **Rationale:** Emphysema is a COPD phenotype with important prognostic implications.
4 Identifying blood-based biomarkers of emphysema will facilitate early diagnosis and
5 development of targeted therapies.

6

7 **Objectives:** Discover blood omics biomarkers for chest CT-quantified emphysema and
8 develop predictive biomarker panels.

9

10 **Methods:** Emphysema blood biomarker discovery was performed using differential gene
11 expression, alternative splicing, and protein association analyses in a training set of 2,370
12 COPDGene participants with available whole blood RNA sequencing, plasma SomaScan
13 proteomics, and clinical data. Validation was conducted in a testing set of 1,016 COPDGene
14 subjects. Since low body mass index (BMI) and emphysema often co-occur, we performed a
15 mediation analysis to quantify the effect of BMI on gene and protein associations with
16 emphysema. Elastic net models were also developed in the training sample sequentially using
17 clinical, complete blood count (CBC) cell proportions, RNA sequencing, and proteomic
18 biomarkers to predict quantitative emphysema. Model accuracy was assessed in the testing
19 sample by the area under the receiver-operator-characteristic-curves (AUROC) for subjects
20 stratified into tertiles of emphysema severity.

21

22 **Measurements and Main Results:** 4,913 genes, 1,478 isoforms, 386 exons, and 881
23 proteins were significantly associated with emphysema (*FDR 10%*) and yielded 109
24 biological pathways. 75% of the genes and 77% of the proteins associated with emphysema
25 showed evidence of mediation by BMI. The highest-performing predictive model used

26 clinical, CBC, and protein biomarkers, distinguishing the top from the bottom tertile of
27 emphysema with an AUROC of 0.92.

28

29 **Conclusions:** Blood transcriptome and proteome-wide analyses reveal key biological
30 pathways of emphysema and enhance the prediction of emphysema.

50

51 INTRODUCTION

52 Chronic obstructive pulmonary disease (COPD) is a leading cause of morbidity and
53 mortality (1). Emphysema, the anatomic destruction of lung parenchyma frequently observed
54 in COPD subjects, has been independently associated with an increased risk for
55 cardiovascular disease, lung cancer, and mortality (2-4). Timely diagnosis calls for a blood-
56 based predictive model as it may identify emphysema in subjects where computed
57 tomography (CT) scans are not clinically indicated. Emphysema blood biomarkers would
58 also overcome the issues of radiation exposure and false positive findings associated with CT
59 scans (5). In addition, early disease biomarkers and a stronger understanding of the molecular
60 basis of emphysema are needed to develop novel personalized therapies to improve the
61 prognosis of affected individuals (2, 6, 7).

62 Previous transcriptomic studies have identified emphysema-associated genes (such as
63 *COL6A1*, *CDI9*, *PTX3*, and *RAGE*) and biological processes (such as innate and adaptive
64 immunity, inflammation, and tissue remodeling) primarily from gene expression analyses
65 using lung tissue samples (8-12). However, fewer studies have evaluated the associations of
66 emphysema with blood transcriptomics, alternative splicing, or proteomics. Alternative
67 splicing, the regulatory process in which multi-exon human genes are expressed in multiple
68 transcript isoforms, has been implicated in the pathophysiology of several lung diseases such
69 as asthma, pulmonary fibrosis, pulmonary arterial hypertension, and COPD (13-19). Protein
70 levels have also been studied for potential emphysema biomarker identification, and sRAGE,
71 ICAM1, CCL20, and adiponectin levels in blood and eotaxin levels in bronchoalveolar
72 lavage fluid were found to be associated with emphysema (20-23), though the protein panels
73 used for these studies included fewer proteins than the more recently developed panels.
74 Finally, previous research that used blood-based emphysema predictive models had small
75 sample sizes and only tested one 'omic modality at a time (20, 24-27).

76 We hypothesized that 1) transcriptomic and proteomic characterization of smokers
77 would elucidate emphysema pathobiology and yield novel disease biomarkers, 2) many
78 emphysema associations with transcripts and proteins are influenced by BMI, and 3) multi-
79 omic modeling would provide improved prediction of emphysema relative to readily
80 available clinical variables. To test these hypotheses, we analyzed whole-blood genome-wide
81 RNA sequencing (RNA-seq) and plasma SomaScan proteomic data from the large and well-
82 phenotyped COPDGene study. Given the high clinical correlation between emphysema and
83 BMI (28), we performed mediation analysis to understand the influence of BMI on
84 emphysema-associated genes and proteins. We also developed machine learning predictive
85 models for emphysema using transcriptomic and proteomic biomarkers. Some of these results
86 have been previously reported as an abstract (29) and a preprint (30).

87

88 **METHODS**

89

90 *Study description*

91 Participants were recruited from the COPDGene study (NCT00608764,
92 www.copdgene.org), a longitudinal study investigating the genetic basis of COPD. The
93 COPDGene population consists of 10,371 non-Hispanic white and African American
94 subjects, 44-90 years old with an average of 44 pack-years of lifetime cigarette smoking
95 history (31). Subjects had varying degrees of COPD severity, as measured by the Global
96 Initiative for Chronic Obstructive Lung Disease (GOLD) grading system. COPDGene
97 obtained 5-year follow-up data and is currently obtaining 10-year follow-up data of available
98 subjects. Questionnaires, chest CT scans, and spirometry have been gathered at 21 clinical
99 facilities in the United States. RNA-seq and plasma proteomic measurements were obtained
100 from a subset of subjects at their 5-year follow-up visit (Visit 2). Each center acquired

101 institutional review board approval and written informed consents. In our analyses, we used
102 the COPDGene Visit 2 data, which included 3,386 subjects with available clinical, RNA-seq,
103 and SomaScan proteomic data.

104

105 ***Emphysema quantification***

106 Using the Thirona software (www.thirona.eu), emphysema was quantified as the 15th
107 percentile of the attenuation histogram + 1,000 Hounsfield units (HU), corrected for the
108 inspiratory depth variations using Multi-Ethnic Study of Atherosclerosis normative equations
109 (predicted lung volume using baseline age, time-varying height, and BMI) (adjusted Perc15
110 density) (32-34). This correction was made since it had been demonstrated to provide a more
111 robust measure of longitudinal changes in emphysema (33).

112

113 ***Training and testing samples***

114 We randomly partitioned our studied cohort into training and testing samples
115 comprising 70% and 30% of the subjects, respectively. All association and mediation
116 analyses, as well as prediction model training, were conducted using the training sample. The
117 validation of the identified biomarkers and constructed predictive model was carried out in
118 the testing sample.

119

120 ***RNA isolation, library preparation, filtering, and normalization***

121 Illumina sequencers were utilized to obtain gene, isoform, and exon counts from total
122 blood RNA isolated from Visit 2 participants. Genomic features with very low expression
123 (average counts per million (CPM) < 0.2 or number of subjects with CPM < 0.5 less than 50)
124 or extremely highly expressed genes (number of subjects with CPM > 50,000 less than 50)
125 were filtered out prior to applying trimmed mean of M values normalization from edgeR

126 (v3.24.3), which accounts for differences in sequencing depth (35). Counts were transformed
127 to log₂ CPM values and quantile-normalized to further remove systematic noise from the
128 data.

129

130 ***Protein measurements and filtering***

131 At Visit 2, plasma samples were assayed for 4,979 proteins using the SomaScan
132 Human Plasma 5.0K assay, a multiplex aptamer-based assay (SomaLogic, Boulder,
133 Colorado) (36). The SomaScan data was standardized per the SomaLogic protocol to control
134 for inter-assay variation between analytes and batch differences between plates (37). Samples
135 with low volume, failed hybridization control, or failed dilution scale were removed.
136 Proteomic data for 5,670 participants passed quality control. The protein counts were
137 transformed to log₂ RFU (relative fluorescent units) values.

138

139 ***RNA-seq differential expression, usage, and protein association analyses***

140 We used the limma-voom linear modeling approach (as implemented in limma
141 v3.38.3) to test for the associations between emphysema and whole blood RNA transcripts
142 (38, 39). The diffSplice function from limma was used to test for differential usage of
143 isoforms and exons. While differential expression refers to the change in the *absolute*
144 expression levels of a feature, differential usage captures alternative splicing and refers to the
145 change in the *relative* expression levels of the isoforms/exons within a given gene. The
146 associations of the SomaScan proteins with emphysema were tested using multivariable
147 linear modeling. In the emphysema “primary” model, we adjusted for age, race, sex, pack-
148 years of smoking, current smoking status, forced expiratory volume in one second (FEV₁),
149 complete blood count (CBC) cell proportions, CT scanner model, and library preparation
150 batch for RNA-seq or clinical center for proteins. The validation rate in the testing sample

151 was determined based on a threshold P-value < 0.1 and a consistent direction of effect in the
152 training and testing datasets. A sensitivity analysis was performed in which the list of
153 covariates from the primary model was expanded to include BMI. To select biomarkers for
154 inclusion in the prediction model, we ran additional models only adjusted for the technical
155 factors (CT scanner model and library preparation batch for RNA-seq or clinical center for
156 proteins). Multiple comparisons were corrected with the Benjamini-Hochberg method using a
157 threshold of significance of a false discovery rate (FDR) of 10% (40).

158

159 ***Mediation analysis***

160 We conducted mediation analysis using the medflex R package (41) to distinguish
161 how much of the effect of emphysema on gene expression or protein levels acted through
162 BMI (referred to as the indirect effect) and how much of the effect of emphysema directly
163 influenced gene expression or protein levels (referred to as the direct effect). The analysis
164 was performed on the significant genes and proteins identified in the primary association
165 analysis. A mediated proportion representing the ratio of the indirect effect over the total
166 effect was computed for each gene with significant total effect. The P-values of the direct,
167 indirect, and total effects for each biomarker were subject to a threshold significance of 10%
168 FDR.

169

170 ***Gene set enrichment analyses***

171 The biological enrichment of the gene sets derived from the gene expression,
172 transcript usage, and protein association analyses was evaluated using the topGO (v2.33.1)
173 weight01 algorithm, which accounts for the dependency in the Gene Ontology (GO) topology
174 (42). We only reported GO pathways with at least three significant genes and an adjusted P-
175 value < 0.005 .

176

177 ***Predictive modeling***

178 We constructed elastic net models to predict cross-sectional emphysema (43). The
179 outcome variable was the adjusted Perc15 density. We utilized clinical variables that are
180 readily available in the primary care setting (age, race, sex, BMI, pack-years of smoking, and
181 current smoking status), CBC (proportions of neutrophils, eosinophils, monocytes,
182 lymphocytes, and platelets), and the RNA-seq and proteins that reached statistical
183 significance in the association analyses performed in the training data (adjusted only for the
184 scanner model and library preparation batch or clinical center). To determine the top
185 performing RNA data type to be used in the main models, we first constructed models using
186 clinical + gene, clinical + isoform, and clinical + exon counts. We then constructed models in
187 the following order: clinical only, clinical + CBC, clinical + CBC + RNA-seq, clinical +
188 CBC + proteins, and clinical + CBC + RNA-seq + proteins. The outcome and the predictors
189 were centered and scaled. The models were trained using 10-fold cross-validation,
190 minimizing the mean squared error (44) on the left-out fold. After model training on the
191 continuous emphysema variable, we classified subjects into tertiles of adjusted Perc15
192 density. We evaluated the predictive performances of the models in the testing sample using
193 R^2 for the continuous emphysema and the area-under-receiver-operator-characteristic curve
194 (AUROC) for the model accuracy to distinguish subjects in the highest and lowest tertiles of
195 emphysema severity. We compared the AUROCs with the DeLong test using the pROC R
196 package (45). Finally, predictors were ranked by the absolute values of their coefficients from
197 the regression model.

198

199 ***Statistical analysis***

200 Data were reported as means with standard deviations or counts with percentages.
201 Continuous variables were tested with Kruskal-Wallis and categorical variables were tested
202 with chi-square. Upregulated versus downregulated genes as well as positive versus negative
203 signs of the protein coefficients are provided with respect to their relationships with adjusted
204 Perc15 density (i.e., negative coefficients indicate a greater extent of emphysema).

205

206 Additional methods are available in the Supplement.

207

208 **RESULTS**

209

210 *Subject characteristics*

211 3,386 subjects from COPDGene Visit 2 with complete clinical, RNA-seq, and protein
212 data were included in our analyses (Figure 1). As shown in Table 1, the included subjects
213 were mostly non-Hispanic whites with a balanced representation by sex, a mean age of 65, a
214 mean BMI of 29, and a mean of 41 pack-years of smoking. The subjects' characteristics did
215 not significantly differ between the training and testing data, which consisted of 2,370 and
216 1,016 subjects, respectively. A comparison of subjects with and without missing data showed
217 that the two groups were largely similar (Table E1). A schematic overview of the analyses
218 performed is illustrated in Figure E1.

219

220 *Differential gene expression analysis*

221 We performed differential gene expression (DGE) analysis in the 2,370 subjects of
222 the training dataset. 4,913 out of 19,177 genes reached significance at 10% FDR (Table
223 2 and E2). 2,339 genes were up-regulated and 2,574 were down-regulated with respect to
224 adjusted Perc15 density (i.e., they have opposite directions for their associations with

225 emphysema) (Figure 2A). The GO enrichment analysis identified 44 significantly enriched
226 biological processes, including neutrophil degranulation, regulation of NF- κ B signaling, viral
227 transcription, T cell proliferation, and regulation of TNF-mediated signaling (Tables 3 and
228 E3).

229

230 ***Differential isoform and exon usage analyses***

231 We next performed differential isoform usage (DIU) and differential exon usage
232 (DEU) analyses on the training dataset to investigate the changes in relative isoform and exon
233 levels within single parent genes. Out of 78,837 isoforms and 209,707 exons tested, 1,478
234 isoforms and 368 exons reached significance (*FDR 10%*) (Table 2). The differentially used
235 isoforms mapped to 1,209 individual genes (Table E4), 45% of which (542/1,209) were also
236 identified in the DGE analysis. The differentially used exons mapped to 251 genes (Table
237 E5), 68% of which (171/251) were also differentially expressed. 53% (788/1478) of the
238 significant isoforms and 66% (244/368) of the significant exons were up-regulated with
239 respect to adjusted Perc15 density (Figure 2B, 2C). The GO enrichment analyses performed
240 on the differentially used isoforms and differentially used exons yielded 35 and 13
241 significantly enriched biological processes, respectively. Top processes included mitophagy,
242 regulation of NF- κ B signaling, negative regulation of WNT signaling, and viral transcription
243 (Table 3, E6 E7).

244

245 ***Protein association analysis***

246 We tested 4,979 SomaScan proteins measured in the training dataset using
247 multivariable linear regression. 18% (881/4,979) were significantly associated with
248 emphysema (*FDR 10%*) (Table E8, Figure E2). Seventeen significantly enriched biological
249 processes were identified, including pathways related to classical complement pathway and

250 WNT signaling (Table E9). Figure 3 summarizes the overlap of the biomarkers and GO terms
251 between DGE, DIU, DEU, and protein analyses, showing that most of the significant
252 biomarkers and enriched pathways are unique to each analysis.

253

254 ***Validation***

255 We analyzed 1,016 subjects with RNA-seq and proteomic data in the testing sample
256 to provide independent validation of the emphysema biomarkers identified in the training
257 sample. We observed that the effect sizes were highly correlated between the analyses
258 performed in the training and testing data for the DGE, DEU, and protein analyses (Pearson's
259 $r = 0.80, 0.86,$ and $0.88,$ respectively). A lower correlation ($r = 0.29$) was observed in the
260 DIU analysis. We further determined whether biomarkers were validated by using a threshold
261 of (testing) P-value < 0.1 and checking if the training and testing data had a consistent
262 direction of effect. Respectively, 46% (2,252/4,913), 30% (449/1,478), 60% (233/368), and
263 47% (416/881) of the DGE, DIU, DEU, and protein biomarkers were validated (Tables E2,
264 E4, E5, and E8).

265

266 ***Mediation analysis***

267 Since severe emphysema is often associated with low BMI, we performed sensitivity
268 analyses that also adjusted for BMI. We observed that 96% (4,728/4,913) of the genes and
269 80% (703/881) of the proteins (Figure E3) associated with emphysema from the primary
270 analysis were no longer significant after adjustment for BMI (Tables E10 and E11). These
271 observations suggest that BMI mediates many of the emphysema-associated transcriptomic
272 and proteomic changes. To investigate this, we performed mediation analysis based on the
273 directed acyclic graph (DAG) (Figure E4) to divide each observed biomarker association into
274 a direct pathway (emphysema directly affects gene/protein expression) and an indirect

275 pathway (emphysema affects gene/protein expression via its effects on BMI). Of the 4,913
276 differentially expressed genes and 881 proteins that reached significance in the primary
277 model (i.e., no BMI adjustment), 70% of genes (3,456/4,913) and 61% of proteins (537/881)
278 showed evidence of mediation with a significant indirect effect and no significant direct
279 effect (*FDR 10%*) (Tables E12 and E13).

280

281 **Prediction**

282 To select blood biomarkers for inclusion in cross-sectional predictive models for
283 emphysema, we performed association analyses in the training dataset, adjusting only for
284 technical factors, which yielded 13,066 genes, 4,254 isoforms, 2,263 exons, and 1,719
285 proteins that were used as candidate predictors. To evaluate whether RNA-seq is more
286 informative at the gene, isoform, or exon level, we trained three separate models (clinical +
287 gene, clinical + isoform, and clinical + exon). The AUROCs were 0.86, 0.74, and 0.86,
288 respectively (Table E14 and Figure E5). Although no statistical significance was attained, a
289 slightly higher AUROC was achieved with the genes compared to exons. Accordingly, we
290 focused on gene-level quantifications for the subsequent models. We next evaluated the
291 relative contribution of CBC proportions, genes, and proteins compared to a baseline model
292 using clinical variables alone. The model using only clinical variables explained 35% of the
293 variance of emphysema. Substantial improvement was seen from adding gene and protein
294 data respectively ($R^2 = 0.38$ for clinical + CBC + gene and 0.50 for clinical + CBC + protein,
295 Table E14). The model with clinical + CBC + gene + protein data did not perform as well as
296 the model with clinical + CBC + protein data. The same pattern was seen when we evaluated
297 model performance for distinguishing subjects in the top versus bottom emphysema tertile;
298 the highest-performing model was the clinical + CBC + protein model with an AUROC of

299 0.92. Figure 4 summarizes the model results, and Table E14 summarizes the AUROCs,
300 alphas, and L1 ratios.

301 Ranked by absolute beta coefficients, the top-10 predictors of the all-inclusive
302 (clinical + CBC + gene + protein) model included BMI, sRAGE, and two biomarkers that
303 have not been previously linked to emphysema (the *MIR124-1HG* gene and the PSMP
304 protein) (Figure 5).

305

306 **DISCUSSION**

307 In this study, we performed the largest blood transcriptomic and proteomic profiling
308 of CT-quantified emphysema to date, including investigations into alternative splicing
309 mechanisms, identifying thousands of validated blood biomarker associations. The biological
310 relevance of these findings was assessed through GO pathway analyses, which mostly
311 demonstrated enrichment for inflammatory pathways and cell differentiation. Mediation
312 analysis revealed that 70% of the differentially expressed genes and 61% of the associated
313 proteins are mediated through BMI, implying that blood biomarker associations to
314 emphysema largely reflect shared biological processes with BMI. We also demonstrated the
315 utility of incorporating multi-omics data in enhancing the prediction of emphysema.

316 In previous biomarker studies of emphysema, the extracellular matrix (ECM), NF- κ B,
317 transforming growth factor beta (TGF- β), B cell antigen receptor (BCR), and oxidative
318 phosphorylation pathways were among the most frequently reported emphysema-associated
319 pathways (8, 46, 47). However, most of these studies focused on a single 'omics modality
320 (20, 24, 48). Our investigation of blood-based transcriptomic and proteomic biomarkers
321 supported numerous established emphysema-associated pathways and discovered new ones.
322 In addition, our alternative splicing analysis for the first time revealed widespread evidence
323 of alternative splicing associated with emphysema.

324 Most blood biomarker associations with emphysema occur through BMI, as indicated
325 by the significant mediation of the tested genes and proteins. This suggests that some of the
326 molecular processes identified in this analysis may be causally related to both emphysema
327 and BMI. We must keep in mind, though, that our mediation analysis is based on the
328 following assumptions: no unmeasured confounding of the emphysema-BMI-gene
329 expression/protein level relationship, no measurement error for the exposure or mediator, and
330 the arrows in the DAG are correctly specified. While our specified DAG is reasonable based
331 on prior knowledge, there are other plausible alternatives DAGs, but no currently available
332 methods to simultaneously test these possibilities.

333 CT scan is the best non-invasive method for detecting emphysema. However, CT has
334 several drawbacks, including increased costs, radiation exposure, and high rates of unrelated
335 false-positive findings (5). Accurate risk prediction tools that use the best available data
336 sources to stratify patients based on their specific risk profiles could help with more efficient
337 early and targeted interventions. Until recently, such prediction models were only created
338 using data from a single 'omics type with or without standard clinical features (49-52). As the
339 first study to utilize genes, alternative splicing, and proteins combined with clinical and CBC
340 predictors, we developed models that could classify upper and lower tertiles of emphysema
341 severity with good accuracy. While alternative splicing predictors were worth exploring, gene
342 data had a higher AUROC. While genes outperformed clinical and CBC features, protein
343 predictors yielded the best AUROC across all models.

344 From the top 10 predictors of the clinical + CBC + gene + protein model, sRAGE,
345 which minimizes tissue injury and inflammation, has consistently been recognized as a
346 candidate emphysema biomarker (5, 10, 53, 54). Not previously connected to emphysema,
347 PSMP has been implicated in inflammation and cancer development (55, 56) and *MIR124-*

348 *IHG* has been shown to affect Wnt-signaling and inflammation (57-60). Their putative roles
349 and functions in emphysema require further investigation.

350 This study has several strengths. The large sample size allowed us to identify many
351 more significant associations than any previous study, and we could split our sample to allow
352 for the validation of our findings. This is the first study that has examined alternative splicing
353 mechanisms in emphysema in addition to differential gene expression and protein association
354 analyses. Because emphysema often co-occurs with low BMI, we performed mediation
355 analyses to better understand the relationship between molecular markers, emphysema, and
356 BMI, providing suggestive evidence of shared biology between emphysema and BMI.
357 Finally, we were able to improve emphysema prediction models with the use of multi-omic
358 data.

359 This study also has several limitations. Complete blood count quantifications do not
360 capture the variability of the immune cell subpopulations, which limits the ability to localize
361 these effects to specific cell types. Future studies may address this by using single-cell
362 transcriptomics data. Limitations to the SomaScan proteomics include the lack
363 of SOMAmers for small molecules such as desmosine, fibrinogen degradation product (Aa-
364 Val360, a specific product generated by elastase cleavage of fibrinogen), and sphingomyelin,
365 which have been suggested to be emphysema biomarkers in other studies (37, 60-62). Lastly,
366 the mediation analysis needs to be viewed as hypothesis-generating since it is based on a
367 number of assumptions.

368

369 **CONCLUSION**

370 Our transcriptomic and proteomic analyses yielded numerous inflammatory and cell
371 differentiation pathways connected to emphysema as well as novel potential blood
372 biomarkers of the disease. While not yet ready to be used in clinical practice, with further

373 validation, our prediction model might be helpful as a less invasive indicator of emphysema
374 severity that could guide patient enrollment in clinical trials. Future research is necessary to
375 compare blood and lung tissue biomarkers, understand how they change as emphysema
376 progresses, and evaluate the impact of implementing these predictive models to personalize
377 and improve patient care.

Participant characteristics reported here are from Visit 2, when 'omics data were obtained.			
Continuous variables are expressed as means and standard deviations. Categorical variables are expressed as absolute values and/or percentages.			
Adjusted Perc15 density: Hounsfield units at the 15 th percentile of CT density histogram at total lung capacity, corrected for the inspiratory depth (per convention, adjusted Perc15 density values are reported as HU + 1000); CAD: Self-reported history of coronary artery disease; Exacerbation history: At least one COPD exacerbation (acute worsening of respiratory symptoms that required systemic steroids and/or antibiotics) in the previous year; FEV ₁ : Forced expiratory volume in one second; GOLD: Global Initiative for Chronic Obstructive Lung Disease; GOLD 1: FEV ₁ /FVC < 0.70 and post-bronchodilator FEV ₁ ≥ 80% predicted; GOLD 2: FEV ₁ /FVC < 0.70 and post-bronchodilator FEV ₁ 50-79% predicted; GOLD 3: FEV ₁ /FVC < 0.70 and post-bronchodilator FEV ₁ 30-49% predicted; GOLD 4: FEV ₁ /FVC < 0.70 and post-			

bronchodilator $FEV_1 < 30\%$ predicted; MMRC: Modified medical research council dyspnea scoring system; Pi10: Square root of the wall area of a hypothetical airway of a 10-mm internal perimeter; PRISm: Preserved Ratio Impaired Spirometry (defined as $FEV_1/FVC \geq 0.70$ but with $FEV_1 < 80\%$ predicted); Race: Self-reports as either non-Hispanic white (NHW) or African American; SGRQ: St. George's Respiratory Questionnaire.

Table 2. Top 5 differentially expressed genes (DGE), differentially used isoforms (DIU), and differentially used exons (DEU) associated to adjusted Perc15 density.

	ID	HUGO Gene Name	Log Fold Change	Average Log Expression	FDR

Adjusted Perc15 density: Hounsfield units at the 15th percentile of CT density histogram at total lung capacity, corrected for the inspiratory depth (per convention, adjusted Perc15 density values are reported as HU + 1000). The lower the Perc15 values are, the more CT-quantified emphysema is present.

For the DGE, DIU, and DEU analyses, the covariates used were age, race, sex, pack-years of smoking, current smoking status, forced expiratory volume in one second (FEV₁), CBC cell count proportions, library preparation batch, and CT scanner model. A threshold of FDR 10% was applied.

Genes and isoforms are represented by their Ensembl Gene ID and Ensembl Transcript ID, respectively. Exonic part IDs with genomic positions are available in Supplemental Table E2. HUGO Gene Name corresponds to the unique gene identified by the Ensembl Gene ID (DGE), and the gene associated with the isoform or exon (DIU and DEU). Log fold change values indicate change per unit increase in adjusted Perc15. Positive log fold change values represent upregulated genes, while negative ones correspond to downregulated ones with respect to adjusted Perc15 density (i.e., they have opposite signs for their associations with emphysema). Average log expression is the average of the log-transformed counts of the gene in analyzed subjects.

Table 3. Selected top 10 gene ontology (GO) biological processes enriched in differentially expressed genes (DGE), differentially used isoforms (DIU), and differentially used exons (DEU) associated to adjusted Perc15 density. GO terms were selected based on potential biological relevance to emphysema.

	GO.ID	GO Term	Total number of genes in category	Number of adjusted Perc15 density-associated genes in category	Adjusted P-value
DGE	GO:0006614	SRP-dependent cotranslational protein targeting to membrane	99	72	2×10^{-21}
	GO:0006413	Translational initiation	185	97	2×10^{-19}

Adjusted Perc15 density: Hounsfield units at the 15th percentile of CT density histogram at total lung capacity, corrected for the inspiratory depth (per convention, adjusted Perc15 density values are reported as HU + 1000). The lower the Perc15 values are, i.e., the closer to -1,000 HU, the more CT-quantified emphysema is present.

For the DGE, DIU, and DEU analyses, covariates used were age, race, sex, pack-years of smoking, current smoking status, forced expiratory volume in one second (FEV₁), CBC cell count proportions, library preparation batch, and CT scanner model.

We only reported the GO pathways with at least 3 significant genes. Enriched GO terms were identified using the weighted Fisher's test P-values < 0.005. Selected GO terms with the lowest P-values in the DGE, DIU, and DEU analyses are listed. Total number of genes in category refers to all genes studied that fall under the GO term. The number of adjusted Perc15-associated genes in category refers to the genes that reached significance (*FDR 10%*) in the DGE, DIU, and DEU analyses.

Table 4. Mediated proportions and direct, indirect, and total effects of the top 5 most and least mediated differentially expressed genes significantly associated to adjusted Perc15 density.

	Ensembl Gene ID	HUGO Gene Name	Mediated Proportion	Direct Effect		Indirect Effect		Total Effect	
				Beta Coefficient	FDR	Beta Coefficient	FDR	Beta Coefficient	FDR
Most mediated genes (genes with significant indirect effect)	ENSG00000160179	<i>ABCG1</i>	0.822	-0.001	0.324	-0.005	1×10^{-31}	-0.006	2×10^{-18}
	ENSG00000169877	<i>AHSP</i>	0.882	0.001	0.559	0.009	4×10^{-31}	0.011	7×10^{-15}
	ENSG00000118113	<i>MMP8</i>	1.054	-0.001	0.859	0.010	4×10^{-26}	0.009	1×10^{-9}
	ENSG00000158578	<i>ALAS2</i>	0.912	0.001	0.724	0.008	1×10^{-24}	0.009	3×10^{-11}
	ENSG00000119326	<i>CTNNA1</i>	0.928	0.000	0.795	0.006	3×10^{-24}	0.007	1×10^{-10}
Least mediated genes (genes with significant direct effect)	ENSG00000189430	<i>NCR1</i>	-0.124	-0.004	1×10^{-4}	4×10^{-4}	0.318	-0.003	2×10^{-6}
	ENSG00000179841	<i>AKAP5</i>	0.129	-0.004	0.002	-7×10^{-4}	0.199	-0.005	8×10^{-9}
	ENSG00000165071	<i>TMEM71</i>	0.094	-0.001	0.002	-1×10^{-4}	0.374	-0.001	5×10^{-8}

	ENSG00000162909	<i>CAPN2</i>	-0.217	0.001	0.002	-2×10^{-4}	0.128	0.001	5×10^{-5}
<p>Mediation analysis was performed to distinguish how much of the effect of emphysema on gene expression acted through BMI (referred to as the indirect effect) and how much of the effect of emphysema directly influenced gene expression (referred to as the direct effect). Covariates: BMI, sex, age, race, pack-years of smoking, current smoking status, and forced expiratory volume in one second (FEV₁).</p> <p>Mediated proportions of top 5 genes are listed along with the coefficients and false discovery rates (FDR) of their direct, indirect, and total effects. Mediated proportion is defined as the ratio of indirect effect to the sum of the indirect and direct effects. Genes are sorted in order of decreasing FDR for the total effect.</p>									

FIGURE LEGENDS

Figure 1. COPDGene Visit 2 participant flow diagram. Abbreviations: AA = African American, CBC = Complete blood count, DGE = Differential gene expression, DIU = Differential isoform usage, DEU = Differential exon usage, FEV₁ = Forced expiratory volume, NHW = Non-Hispanic White.

Figure 2. Volcano plots of the primary model representing (A) differentially expressed genes (B) differentially used isoforms, and (C) differentially used exons. Genes significantly associated with adjusted Perc15 density appear above the red line marked at FDR 10%. Up-regulated genes are in blue and down-regulated genes are in red. Isoforms/exons that are not differential used are gray and appear below the threshold line. Adjusted Perc15 density: Hounsfield units at the 15th percentile of CT density histogram at total lung capacity, corrected for the inspiratory depth (per convention, adjusted Perc15 density values are reported as HU + 1000). The lower the Perc15 values are, the more CT-quantified emphysema is present. Upregulated versus downregulated genes are reported with respect to adjusted Perc15 density (i.e., they have opposite directions for their associations with emphysema).

Figure 3. (A) Number of significant genes associated with adjusted Perc15 density from the differential gene expression (DGE), differential isoform usage (DIU), differential exon usage (DEU), and protein association analyses. HUGO gene symbols were used to find the intersection of biomarkers between the DGE, DIU, DEU, and protein analyses. Multiple proteins may map to a single gene. Therefore, the diagram does not reflect the total number of proteins significantly associated with adjusted Perc15 density. (B) Number of significant enriched gene ontology (GO) terms from the DGE, DIU, DEU, and protein association analyses. Adjusted Perc15 density: Hounsfield units at the 15th percentile of CT density

histogram at total lung capacity, corrected for the inspiratory depth (per convention, adjusted Perc15 density values are reported as HU + 1000). The lower the Perc15 values are, the more CT-quantified emphysema is present. Upregulated versus downregulated are reported with respect to adjusted Perc15 density (i.e., they have opposite directions for their associations with emphysema).

Figure 4. The receiver operating characteristic curves for the elastic net prediction models: clinical (age, race, sex, BMI, pack-years of smoking, and current smoking status) only, clinical + complete blood count (CBC) proportions of neutrophils, eosinophils, monocytes, lymphocytes, and platelets, clinical + CBC + genes, clinical + CBC + proteins, and clinical + CBC + genes + proteins. The table summarizes the pairwise DeLong P-values of the model comparisons. P-values < 0.05 are bolded.

Figure 5. Top 10 predictors sorted in descending order by the absolute values of their beta-coefficients from the elastic net model using clinical (age, race, sex, BMI, pack-years of smoking, and current smoking status), complete blood count (CBC) proportions of neutrophils, eosinophils, monocytes, lymphocytes, and platelets, gene, and protein data. The horizontal lines represent the magnitude of the coefficient for each feature. All predictors were centered and scaled.
