

Concurrent 3D super resolution on intensity and segmentation maps improves detection of structural effects in neurodegenerative disease: Supplementary information

author

26 May, 2022

1 Supplementary Information Overview

This document provides supplemental information to the main article detailing:

- the software stack;
- data licenses/acknowledgements;
- pointers to example data and its download location;
- the code used in data generation and training;
- training the quality prediction ResNet;
- the code for evaluating segmentation performance in simulated (downsampled) data;
- cohort details for each diagnostic group;
- the a priori regions selected for each diagnostic group;
- the source data for key results;
- other performance implications with respect to individual regions and diagnoses.

Each point outlined above will be covered in a specific sub-section following the same (shortened) title. The download location for the majority of the supplemental resources, data and tables is at [this link](#). The data location may be referenced via [DOI:10.6084/M9.FIGSHARE.19848670.V13](https://doi.org/10.6084/M9.FIGSHARE.19848670.V13) [1]. NOTE: this DOI is versioned; e.g. V13 can be updated to V14 when changes are necessary. Please check that you have the latest version.

1.1 List of included resources

The resources at the above link include:

- `demog.csv` - the basic demographic data for 4RTNI and NIFD subjects
- `mindboggle_sr_test.py` - example segmentation evaluation code and super-res code.
 - this script was used to generate data in Table 1 and Figure 4
- `OASIS-TRT-20-9_gt_img.nii.gz` - the example T1w MRI used in `mindboggle_sr_test.py`
- `OASIS-TRT-20-9_gt_seg.nii.gz` - the example T1w MRI segmentation used in `mindboggle_sr_test.py`
- `neurips_2022_train_SR_fs.R` - model training code.
- `neurips_2022_data_gen_SR_fs.R` - the data generation code.
- `CSRS.R.TV.D.Res6.csv` - the effect size estimates by diagnosis for the best model (Tables 1 and 2), the linear upsampling (worst) model and the original resolution model;
- `CSRS.R.TV.D.h5` - the CSRS model with reconstruction, total variation and Dice losses;
- `CSRS.R.TV.D.Res6.h5` - the CSRS model with reconstruction, total variation, Res6 and Dice losses;

- CSRS.R.TV.VGG.h5 - the model with reconstruction, TV and VGG loss.
- eco_sr_supplemental.Rmd - the source code for this document

2 Software stack

The software stack uses a mix of R (for training and data generation) and `python` for testing and scaled-up application of CSRS and supporting tools. The deep learning core software is `tensorflow`. Most of the R code can be implemented in a near direct translation to `python`. The primary tools are available in the ANTsX software stack [here](#) at [github](#). Docker containers are also available that package the core tools. Several installation and usage options are available and potential users can contact developers for details if they encounter barriers. The ANTsX software stack operates under the Apache license version 2.0. Key packages used in this work:

- [ANTsR](#) commit `ecfb0b32e340c8b596958a8a0561cf4f310903fa` – image processing core tools in R;
- [ANTsRNet](#) commit `dcad84e91e9d2f7808e06d9b735b6475717472ea` – network architectures in R;
- [ANTsPy](#) [pypi release 0.3.2](#) – image processing core tools in `python`;
- [ANTsPyNet](#) [pypi release 0.1.8](#) – network architectures in `python`;
- [ANTsPyT1w](#) [pypi release 0.7.1](#) – image processing standards for volumetric T1-weighted neuroimages in `python`.

These packages have `get_data` commands which supply relevant examples and models for brain image processing.

3 Data Acknowledgments

NIFD and 4RTNI and both available via request from the Laboratory of Neuroimaging (LONI). We do not have permission to redistribute this data in raw or derived form but users can download it and process it themselves with `ANTsPyT1w` (part of the ANTsX ecosystem) available from `pypi`.

NIFD/4RTNI: Data used in preparation of this article were obtained from the Frontotemporal Lobar Degeneration Neuroimaging Initiative (FTLDNI) database <http://4rtni-ftldni.ini.usc.edu>. The investigators at 4RTNI/NIFD/FTLDNI contributed to the design and implementation of FTLDNI and/or provided data, but did not participate in analysis or writing of this report (unless otherwise listed). Data collection and sharing for this project was funded by the Frontotemporal Lobar Degeneration Neuroimaging Initiative (National Institutes of Health Grant R01 AG032306). The study is coordinated through the University of California, San Francisco, Memory and Aging Center. Frontotemporal Lobar Degeneration Neuroimaging Initiative data are disseminated by the Laboratory for NeuroImaging at the University of Southern California.

Data collection and sharing for this project was funded by the 4-Repeat Tauopathy Neuroimaging Initiative (4RTNI) (National Institutes of Health Grant R01 AG038791) and through generous contributions from the Tau Research Consortium. The study is coordinated through the University of California, San Francisco, Memory and Aging Center. 4RTNI data are disseminated by the Laboratory for Neuro Imaging at the University of Southern California.

Data collection and sharing for this project was funded by the Frontotemporal Lobar Degeneration Neuroimaging Initiative (National Institutes of Health Grant R01 AG032306). The study is coordinated through the University of California, San Francisco, Memory and Aging Center. FTLDNI data are disseminated by the Laboratory for Neuro Imaging at the University of Southern California.

PPMI: Data used in the preparation of this article were obtained from the Parkinson’s Progression Markers Initiative (PPMI) database www.ppmi-info.org/access-data-specimens/download-data. For up-to-date information on the study, visit ppmi-info.org. PPMI – a public-private partnership – is funded by the Michael J. Fox Foundation for Parkinson’s Research and funding partners, including 4D Pharma AbbVie

4 Reproducing key results

4.1 pointers to example data and its download location

The repository [DOI:10.6084/M9.FIGSHARE.19848670.V13](https://doi.org/10.6084/M9.FIGSHARE.19848670.V13) contains an example image and segmentation from the **MindBoggle data**. These images can be used with the file `mindboggle_sr_test.py` to implement a basic test of simulated segmentation performance with CSRS. Models `CSRS.R.TV.D.h5`, `CSRS.R.TV.VGG.h5` and `CSRS.R.TV.D.Res6.h5` are available and named as the same way as in the main paper. This same code base is used in the evaluation of 4RTNI and NIFD combined data.

4.2 code for data generation and training

In the same location are two files: `neurips_2022_data_gen_SR_fs.R` and `neurips_2022_train_SR_fs.R`. As names suggest, these provide the code that was used (first) to generate the full training dataset. Once training data is done, we used the `neurips_2022_train_SR_fs.R` code with the parameters described in the text to train the various versions of our models. Key to this is the `T1wQRResNet` which is called `~/antspyt1w/resnet_grader.h5` available from the `antspyt1w` data repository.

4.3 training the quality prediction ResNet (T1wQRResNet)

A key contribution of the article is a new feature space based on a ResNet that predicts T1-weighted neuroimage quality. The network was trained on brain extracted (`antspyt1w.brain_extraction`) PPMI T1w data to predict the A, B, C and F classification labels of quality. The loss function is computed over batches of size 16 with images at $2mm^3$ resolution. Denoting g_t as the true label binary assignment matrix (shape 16×4), g_p as predicted label `softmax` probability matrix (shape 16×4) and g_p^s, g_t^s as the numeric coding of those labels (0,1,2,3) (shape 16×1), then we minimize:

$$m(CCE(g_t, g_p)) - m(pearson(g_t^s, g_p^s)) * \gamma$$

where m indicates a `mean` (or averaging) operation, $\gamma = 0.1$ is a scalar weight, `CCE` is the categorical cross entropy and `pearson` represents the Pearson correlation. We train the network on augmented PPMI data (random small -0 to approximately 15 degree across any axis – rotations of the original images) until convergence where convergence was determined on 5% data left out from training with a balanced distribution across grades.

4.4 evaluating segmentation performance in simulated (downsampled) data

The file `mindboggle_sr_test.py` implements the following steps:

- read images and normalize the intensity

```
imggt = ants.image_read( "mindboggle_image/OASIS-TRT-20-9_gt_img.nii.gz" )
seggt = ants.image_read( "mindboggle_image/OASIS-TRT-20-9_gt_seg.nii.gz" )
imggt = ants.iMath(imggt, "Normalize")
```

- downsample the images to 2mm by nearest neighbor and upsample again by generic label (the reference for standard upsampled segmentation results)

```
img = imggt.resample_image( [2,2,2], use_voxels=False, interp_type=1 )
seg = ants.resample_image( seggt, [2,2,2], use_voxels=False, interp_type=1 )
segup = ants.resample_image_to_target( seg, seggt, interp_type='genericLabel')
intup = ants.resample_image_to_target( img, seggt, interp_type='linear')
```

- calculate PSNR, SSIM and overlap for reference results

```
linpsnr = antspynet.psnr(imggt, intup )
linssim = antspynet.ssim(imggt, intup )
lindice = ants.label_overlap_measures( seggt, segup )
lindice.insert(1,'ssim',linssim)
lindice.insert(1,'psnr',linpsnr)
```

- load the tensorflow model and apply to the low-resolution image and labels

```
srmdl = tf.keras.models.load_model( mdlfn )
ssr = antspyt1w.label_and_img_to_sr(
    img,
    seg,
    srmdl,
    return_intensity=True )
```

- calculate PSNR, SSIM and overlap for CSRS results

```
mypsnr = antspynet.psnr( imggt, ssr['super_resolution'] )
myssim = antspynet.ssim( imggt, ssr['super_resolution'] )
myol = ants.label_overlap_measures( seggt, ssr['super_resolution_segmentation'] )
```

This same code is used in the real world evaluation of neurodegenerative disease.

4.5 source data for the cohort

The cohort description is within `demog.csv`.

4.6 source data for the key result: effect size estimates

The supplementary information focuses on the results contained within the file `CSRS.R.TV.D.Res6.csv` which provides the data associated with the best performing model.

Figure 1: NIFD and 4RTNI group characteristics at baseline.

Figure 1 shows the distribution of baseline characteristics across our diagnostic groups. NOTE: PNFA is equivalent to naPPA; SV is equivalent to svPPA and the “Patient(Other)” group was not used. Figure 2 is the longitudinal cohort description.

5.2 the a priori regions selected for each diagnostic group

We exclude large regions such as caudate and putamen as we do not expect a priori improvements due to PSR. For cortical measurements, we assess both volume and thickness.

We join the PSP and CBS groups as these are highly related diagnoses. In addition, in this supplemental example, we add supramarginal gyrus as a target region for CBS/PSP.

5.3 Sorted comparisons of best regions per diagnosis and per resolution by type of effect (longitudinal or cross-sectional)

The tables below are autogenerated from a function within this compilable document (`eco_sr_supplemental.Rmd`). The function is called `maketables`. Users can modify this to display results in a different way than shown here. these results highlight key regions for each diagnosis and its associated *a priori* hypothesis sets. We focus on the best model `CSRS.R.TV.D.Res6`.

We also display pairwise test results for each diagnosis broken down by longitudinal and cross-sectional groups. Statistical details are shown for each result. Plots are also supplied.

5.3.1 Top n effect sizes and pairwise tests for bvFTD

Regions with the highest effect sizes are relatively unsurprising for these bvFTD subjects. However, the “best” regions for cross-sectional detection may not equal the best for longitudinal detection. This is generally true for all groups/diagnoses.

Table 1: OR bvFTD : regions sorted by cross-sectional effect sizes.

$\log_e(BF_{01}) = -5.03$, $\hat{\delta}_{\text{difference}}^{\text{posterior}} = 0.01$, $CI_{95\%}^{\text{HDI}} [6.06e-03, 0.02]$, $r_{\text{Cauchy}}^{\text{JZS}} = 0.71$

5.4 other performance implications with respect to individual regions and diagnoses

We also examined relationships between the volume or thickness of the input region and the effect size and effect size improvement. Overall, smaller regions tend to show greater improvement, as expected. However, this effect is limited to regions below a given threshold of size. As we do not have a continuous distribution of region size in these data, more work would be needed to identify both size and shape criterion to help determine which types of regions should improve most under CSRS or related SR/PSR methods. These results may vary with the disease and, as such, could be considered in a disease-specific and region-specific manner. It is likely that one could identify results that are superior to those identified here if one used targeted, goal-specific training instead of the disease and region agnostic strategy that we employed.
