

Materials and Methods

1. Study Design

We collected plasma samples from 440 patients diagnosed with 18 distinct types of cancer, as well as from healthy individuals (Fig S1). We focused on early-stage common solid tumours where early detection followed by medical/surgical treatment can significantly enhance the survival of the patients. Then, we used Olink's Proximity Extension Assay technology to measure proteins in the plasma samples. Using the machine learning approaches, we identified protein biomarkers for detection of cancer as well as identification of the site of origin of the cancer.

2. Sample Collection

The EDTA plasma samples used in this analysis were provided by the Ukraine Association of Biobank (UAB). (21) A summary of the number and type of samples is outlined in Table S1. The UAB was established in 2017 with the goal of growing and developing the biobank network across Ukraine. The network encompasses biobanks from the main Institutes of Medical Sciences in the country and operates under the guidance of the ESBB, ISBER, and NCI guidelines. The UAB has established policies and necessary documents such as the Patient Consent Policy, Patient Information Sheet, Biobank Consent Form, and Sample Application Form to ensure ethical and transparent operations in medical institutions and hospitals. UAB places a strong emphasis on maintaining the highest ethical standards in its operations and has implemented strict bioethical policies and state-of-the-art procedures. The anonymity of donors is protected, and they are fully informed about the purpose of medical research and the potential benefits of scientific discoveries through legal consent documentation. All specimens are obtained with the fully informed and signed consent of donors. Every specimen collected by the UAB is processed following a rigorous Standard Operating Procedure (SOP). Quality control is conducted on all collected tissue samples, and the specimens are handled with utmost care and precision from the time of excision to storage and shipment to ensure that the customers receive only the highest quality specimens.

3. Protein Measurement

The protein levels in plasma were determined by utilizing the Olink® Explore 3072 technology. A full description of Olink's Proximity Extension Assay (PEA) technology has been reported elsewhere. The list of the proteins measured, and their characteristics are provided in the Table S2.

Briefly, this technology employs antibody-based detection to assess the levels of 3,072 target proteins in plasma. The antibodies were each conjugated with two complementary probes and divided into four separate 384-plex panels. Each panel included three control assays for quality control purposes (interleukin-6 (IL6), interleukin-8 (CXCL8), and tumour necrosis factor (TNF)). The process began with an overnight incubation to allow the conjugated antibodies to bind to the target proteins in the samples. This was followed by an extension and pre-amplification step, where the hybridization and extension of the complementary probes took place. The extended DNA was then amplified through PCR and indexed to prepare the libraries, which were sequenced using the Illumina NovaSeq platform. The counts obtained from the sequencing were subject to a quality control and normalization procedure, which involved the

use of internal controls to reduce intra-assay variability. These included an incubation control consisting of a non-human antigen, an extension control consisting of a unique pair of probes, and an amplification control consisting of a double-stranded DNA sequence. Additionally, external controls such as a negative control (buffer sample) and plate controls (pool of plasma) were used to determine the limit of detection and adjust levels between plates, respectively. Finally, two known samples were used as sample controls to calculate the precision of the measurements. After quality control and normalization, the data was provided in a Normalized Protein eXpression (NPX) unit, which is on a log₂ scale and indicates a high protein level with a high NPX value.

The analytical performance of Olink's panels has been carefully validated for sensitivity, dynamic range, specificity, precision, and scalability (Table S2). Analytical measuring range was defined by the lower limit of quantification (LLOQ) and upper limit of quantification (ULOQ) and reported in pg/mL. The high dose hook effect (a state of antigen excess relative to the reagent antibodies resulting in falsely lower values) has also been determined for each analyte. All assays have been thoroughly validated for precision (repeatability and reproducibility). Intra-assay variation (within-run) has been calculated as the mean CV for 6 individual samples, within each of 7 separate runs during the validation studies. Inter-assay variation (between-runs) was calculated as the mean CV, for the same 6 individual samples, among 7 separate runs during the validation studies.

4. Biomarker Discovery

We transformed each problem into a binary classification one. For the pan-cancer detection problem, the positive class encompassed all cancer samples, and the control class included normal samples. For the localization of each cancer, the samples of that specific cancer were considered positive cases, while other cancer samples were considered negative cases.

We employed Logistic Regression with an L1 penalty to identify a sparse set of informative biomarkers. Each protein was standardized to zero mean and unit standard deviation to ensure comparable coefficients. The strength of the L1 penalty was determined using stratified 5-fold cross-validation on a logarithmic scale ranging from 1e-4 to 1e4. The desired number of biomarkers was then selected based on the magnitude of their absolute coefficients. The pre-processing and modelling were carried out using the Scikit-learn Python library. (22)

After identifying the biomarkers, linear classifiers were trained on the training data utilizing the selected biomarkers. In the pan-cancer detection component, the predicted probability for each sample is compared to a threshold to determine whether it is normal or cancerous. The threshold is set to attain the desired level of specificity. The positive samples from the detection component then proceed to the localization component, which consists of one model for each type of cancer. The sample is assigned to the class with the highest predicted probability. For data visualization, we used matplotlib (version 3.6.0), (23) seaborn (version 0.12.0), (24) and plotly (version 5.10.0). (25) Pre-processing and modelling were performed in Python (version 3.9.13), using scikit-learn (version 1.1.2), (22) pandas (version 1.4.4), (26) numpy (version 1.23.3), (27) and statsmodels (version 0.13.2). (28)

5. Biomarker Validation

After biomarkers selection and to maximize the use of data in our training models, we used the leave-one-out method as our evaluation method. In this approach, the number of folds equals the

number of instances in the data set. We applied the learning algorithm once for each instance, using all other instances as a training set and using the selected instance as a single-item test set.
