Appendix

1.1 Methods

1.1.1 Outcome definitions

CVD was defined as the occurrence of fatal or non-fatal myocardial infarction (MI), sudden cardiac death, ischemic heart disease, fatal or non-fatal stroke or PAD after the start of follow-up. We additionally considered a broader definition of CVD, also including heart failure (HF) and/or atrial fibrillation (AF): "CVD+HF+AF", as well as the individual CVD components: CHD, stroke, AF, and HF; see Appendix Table 1.

1.1.2 UK Biobank structure

The data fields in the UK Biobank cover multiple time points, and within each time point, a variable maybe be recorded several times. For example, the severity of manic/irritable episodes (data field id = 5674 [1]) was recorded at four-time points: initial assessment visit, first repeat assessment visit, imaging visit, and first repeat imaging visit). The UK Biobank terminology defines each time point as an "instance", and the measurements recorded at a single time point as "arrays". The column format is defined as *field_id – instance.array* [2]. For example, column "5674-0.0" refers to the initial assessment visit, while "5674-1.0" refers to the first subsequent visit. Data field id = 5076 ("Number of letters correct in round (right)" [3]) presents an example where multiple measurements were recorded during a single visit e.g. "5076-0.0", "5076-0.1", "5076-0.2".

Variables types include continuous, integer, categorical (one possible answer), categorical (multiple possible answers), text, time, and compound[4]. Here compound describes a variable type where a set of variables are required to describe some compound property, for example, an applanation curve (describes the reflected light signal from the cornea, field id = 5266). A categorical (one possible answer) field could refer to a binary response (e.g., yes or no), but could also refer to multiple responses from which a participant could only select one. The categorical (multiple possible answers) fields allowed participants to provide multiple answers, for example, the response option to the question "Which of the following do you never eat?" included "eggs", "dairy products", "wheat products", "sugar", "I eat all of the above", or "Prefer not to answer".

1.1.3 Data engineering strategy

We developed a de novo data engineering pipeline, and subsequently performed feature selection using an elastic net algorithm, where identified features were replicated in a 20% independent hold-out set using a permuted change in c-statistics to estimate feature importance. This feature selection pipeline was independently applied to six outcomes: coronary heart disease (CHD), ischemic stroke, heart failure (HF), atrial fibrillation (AF), CVD (combining CHD, stroke, and peripheral arterial disease (PAD)), and a broader definition of CVD+HF+AF, including HF and AF - outcomes which are more common in people with diabetes [5], [6].

The raw UKB data was curated using a purpose-built data-engineering pipeline returning quality-controlled tabular data allowing for subsequent analysis; see Appendix Figure 1. Briefly, the data engineering procedure was split into two parts: 1) basic filtering and standardization: excluding meta-data, non-baseline features, and curating retained fields (e.g., combining information recorded in separate fields, see Appendix Methods, Appendix Figure 2), and 2) type-specific transformation: creating binary variables from categorical fields, removing invariant variables and categories with too few occurrences (Appendix Methods, Appendix Figure 3).

In the *initial filtering and standardization* (Appendix Figure 2) fields were excluded if they did not present data measured at enrolment. Additionally, pilot fields,

representing a subset of the data available in the non-pilot data, and categorical fields with one possible answer, but with multiple data items measured at the same time were removed. Subsequently, data fields containing meta-data, such as time (representing time of measurement), text (representing information such as device type or id) were removed from the analysis. Given the often complex inter-relationship between compound fields, these were excluded from the analysis. Furthermore, country-specific variables not recorded for all considered countries (England, Scotland, Wales) were removed. The mean value was used for continuous (floating point numbers e.g. participant height) and integer (whole number e.g. participant age) fields with multiple measurements at the same assessment visit. Additionally, related data fields also including data fields available for all considered countries were merged; see Appendix Table 3 and Appendix Table 4. For example, a single combine rule links all data fields that measure the participant's weight (data field ids: 3160 (manual entry) from body size measures, 23098 from body composition by impedance) or glucose (data field ids: 30740 from blood chemistry, 23470 from NMR spectroscopy). Next, 98 semantic rules (consisting of conditioning and affected data fields) were manually determined and reviewed (by KD and AFS) to mitigate the issue of missing responses wherever it was possible; see Appendix Table 5. This is due to the nature of the UKB, where not all of the participants were asked the same set of questions, the follow-up question may depend on a participant's previous answer. The semantic rules were defined using a related field to determine a missing value. For example, data field id = 1249 ("Past tobacco smoking") was collected from participants except those who indicated they currently smoke on most or all days, as defined by their answers to data field = 1239 ("Current tobacco smoking"). Finally, procedural responses such as "Do not know" or "Prefer not to answer" were replaced by missing values (Appendix Table 6).

The initial filtering step was followed by a *type-specific transformation* step (Appendix Figure 3 adopted from [7]), where retained data was further processed. For example, continuous data were screened for a percentage of constant values, where fields where more than 20% of participants had the same value, were additionally

scrutinised to determine whether this information might be better represented as binary or categorical coding, or removed entirely. For questions where participants could provide multiple answers the categorical variable was converted to a set of binary indicator variables. For example, for the variable considering reasons of reduced smoking (data field = 6158 [8]), with values "illness or ill health", "doctor's advice", "health precaution", or "financial reasons", I created binary variables e.g. "illness or ill health": $\{\text{True}, \text{False}\}$, or "doctor's advice": $\{\text{True}, \text{False}\}$, and so on.

While the UKB was designed to capture information about all participants, irrespective of possible clinical diagnoses, some of the data is affected by missing data. Furthermore, some of the data fields are only available (by design) for a subset of participants. This issue was partially addressed by the data engineering steps, where a part of the missing values was filled using semantic rules (see Appendix Table 5). Additionally, features that were retained after the data engineering step were screened for the percentage of missingness, excluding categories (i.e., containing multiple variables) where over 40% of the values were missing; see Appendix Tables 2, 7. The dataset was enhanced by basic demographic variables such as age, sex, and country of origin information.

1.1.4 Statistical analysis

In the current analysis we exclusively focussed on measurements which were offered to all participants, with the limited number of missing data points imputed using the R package MICE [9].

After randomly splitting the data into 80% for training, and 20% for testing, the training data was used to prune features which showed a very weak univariable association with the considered outcomes. Specifically, for each of the 6 CVD outcomes we calculated the Spearman's correlation and dropped variables with a p-value equal or larger than 0.80. Subsequently, we identified variables with an absolute pairwise Spearman's correlation of 0.70 or larger – indicative of multicollinearity, dropping one of the variables that made up a multicollinear pair.

1.1.5 Identification of mutually independent features

To identify novel CVD-related features we leveraged a generalized linear model with a binomial distribution and an elastic net penalty (reflecting a combination of L1 and L2 penalty), removing features not associating with the considered outcome. Elastic net models will automatically perform a feature selection step, based on the required regularization necessary to optimize the c-statistic, where for the same number of candidate features but a smaller number of cases the expected regularization will increase (and hence the number of selected features will decrease) [10]. Ten-fold cross-validation, stratified by case (people who developed CVD) and control status (people who did not develop CVD), was used to optimize model hyper-parameters - e.g., to decide on the amount and type (the L1/L2 ratio) of penalization, using the available training data.

1.1.6 Feature importance

The feature importance of each selected variable was evaluated using a permutation feature importance algorithm (using 10 permutations), quantifying the change in the c-statistic. Features were subsequently ranked by their c-statistic change, stratified by outcome type (CVD+AF+HF, CVD, CHD, HF, AF, Isch. Stroke) and a participant group ("wo T2DM/CVD", "w T2DM", "w T2DM&CVD"). To provide an aggregate evaluation of the importance of each feature, we additionally recorded how often a feature was selected in each of the 6 available outcomes and calculated the summed c-statistic per participant group. The feature importance permutation algorithm was applied to the test data to provide independent replication, and as additional assurance against over-fitting. Here we dropped features with a zero or negative feature importance in the test data, indicating a failure to replicate. As age and sex are well-known and dominant CVD risk factors, the main text focussed on the remaining features, noting these remaining features are conditionally independent of age and sex. Performance of age and sex was included along with a complete list of the identified features in the relevant Appendix Tables 8 – 10 and Appendix Data 1.

Next, we identified the rank of features used in any the following three clinically

used prediction models: ASCVD [11], QRISK3 [12] and the Framingham 1998 [13] score. Here we focussed on predicting 10-years risk of CVD, differentiated between whether a variable included in these three models was selected by our feature selection pipeline, and if so what its rank across the three participant groups.

To illustrate the benefit of these novel risk factors for risk classification we calculated the net-reclassification index [14] for the onset of CVD or HF, comparing predictions based on the classical risk factors employed by the ASCVD [11], QRISK3 [12] and the Framingham 1998 [13] models, compared to consideration of both novel and classical risk factors. For these calculations we applied risk cut-offs of below 10% risk, between 10 and 20%, and above 20%, and focussed on the wo T2DM/CVD and w T2DM participant subgroups given that the participants of w T2DM/CVD predominantly received predicted risk above 20%. We calculated the number of cases which appropriately received a higher risk by calculating the difference between the proportion of cases receiving a higher risk and the proportion of cases receiving a lower risk, multiplying the difference by a 1000.

Despite this manuscript not necessarily focussing on deriving a novel prediction model, the models were evaluated in terms of their discriminative (c-statistic) ability using the independent test dataset. The differences in discriminate performance between training and testing were used as a metric of model over-fit, where an overfitted model reflects sample size-specific peculiarities, instead of generalizable findings. This complemented the feature importance estimates calculated on the independent test dataset, which by using the independent test set, were unaffected by any potential model overfit.

1.2 Results

1.2.1 CVD features selected in all three participants groups

To show the commonalities between all three groups, we next identified features that were selected for all three participant subgroups, stratifying by CVD outcome type; Appendix Data 2. The number of common features ranged from 14 for CHD to 44 for AF. For CHD the common features recorded information on familial

disease history (e.g., familial history of heart disease), self-reported general health (e.g. quit smoking due to illness, insomnia, narcolepsy), socio-economic factors (educational attainment), and biochemistry (e.g., HDL-C, urinary microalbumin). For AF common features included anthropometrics (e.g. estimated trunk mass, height), self-reported health (e.g. recent illness or injury), familial disease history (sibling with Parkinson's disease), biochemistry (e.g. urate, albumin, total bilirubin, neutrophil percentage, cystatin C. The HF common features covered socioeconomic factors (e.g., on disability allowance, "housing: renting/owning", unable to work due to illness), biochemistry (e.g. urate, Cystatin C, HbA1c, RBW), self-reported health (e.g. health satisfaction) and familial disease history (e.g. paternal history of dementia, recent illness or injury). For Ischemic stroke the common features included systolic blood pressure, biochemistry (e.g. HbA1c, Cystatin C, testosterone), diet (intake of raw vegetables, intake of cheese, not eating

1.2.2 Difference in discriminative performance between training and testing samples

The elastic net models were derived in a training and testing split, where performance in the test set provides an unbiased estimate of performance, unaffected by potential model over-fitting which would also impact feature selection. To identify potential problematic analyses, affected by over-fitting, we calculated the difference in c-statistic between the training and testing sets, where a large difference is indicative of model over-fit. The difference was smaller than 0.1 for all analyses, aside from a relatively large difference of 0.18 for the model predicting Ischaemic stroke in people with T2DM and CVD at enrolment, which correlated with a small number of cases (316) relative to the number of candidate predictors (238); see Appendix Table 11, Appendix Table 16.

Table 5 – continued from previous page

Conditioning data field	Conditioning triggering values	Affected data field	Baseline value for affected data field
Ever highly irritable/argumentative for 2 days (4653)	(0 : No)	Manic/hyper symptoms (6156)	Not applicable
Ever highly irritable/argumentative for 2 days (4653)	(0 : No)	Severity of manic/irritable episodes (5674)	Not applicable
Ever stopped smoking for 6+ months (2907)	(0 : No)	Likelihood of resuming smoking (2936)	Not applicable
Ever stopped smoking for 6+ months (2907)	(0 : No)	Number of unsuccessful stop-smoking attempts (2926)	Not applicable
Ever stopped smoking for 6+ months (2907)	(0 : No)	Why stopped smoking (6157)	Not applicable
Type of tobacco previously smoked (2877)	(3 : Cigars or pipes)—(7 : None of the above)	Number of cigarettes previously smoked daily (2887)	0
Smoking compared to 10 years previous (3506)	(1 : More nowadays?)—(2 : About the same?)	Why reduced smoking (6158)	Not applicable
Previously smoked cigarettes on most/all days (5959)	(0 : No)	Age stopped smoking cigarettes (current cigar/pipe or previous cigarette smokers) (6194)	Not applicable
Type of tobacco currently smoked (3446)	(1 : Manufactured cigarettes)—(2 : Hand-rolled cigarettes)—(7 : None of the above)	Number of cigarettes previously smoked daily (current cigar/pipe smokers) (6183)	Not applicable
Type of tobacco currently smoked (3446)	(3 : Cigars or pipes)—(7 : None of the above)	Age stopped smoking cigarettes (current cigar/pipe or previous cigarette smokers) (6194)	Not applicable
Type of tobacco currently smoked (3446)	(3 : Cigars or pipes)—(7 : None of the above)	Difficulty not smoking for 1 day (3475)	Not applicable
Type of tobacco currently smoked (3446)	(1 : Manufactured cigarettes)—(2 : Hand-rolled cigarettes)—(7 : None of the above)	Number of cigarettes currently smoked daily (current cigarette smokers) (5456)	Not applicable
Type of tobacco currently smoked (3446)	(1 : Manufactured cigarettes)—(2 : Hand-rolled cigarettes)—(7 : None of the above)	Number of cigarettes previously smoked daily (current cigar/pipe smokers) (6183)	0
Type of tobacco currently smoked (3446)	(1 : Manufactured cigarettes)—(2 : Hand-rolled cigarettes)—(7 : None of the above)	Previously smoked cigarettes on most/all days (5959)	Not applicable
Type of tobacco currently smoked (3446)	(3 : Cigars or pipes)—(7 : None of the above)	Time from waking to first cigarette (3466)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Likelihood of resuming smoking (2936)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Number of cigarettes previously smoked daily (2887)	0
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Number of unsuccessful stop-smoking attempts (2926)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Why stopped smoking (6157)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Age started smoking in former smokers (2867)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Age stopped smoking (2897)	Not applicable
Past tobacco smoking (1249)	(2 : Smoked occasionally)—(3 : Just tried once or twice)—(4 : I have never smoked)	Ever stopped smoking for 6+ months (2907)	Not applicable

Table 5 – continued from previous page

Conditioning data field	Conditioning triggering values	Affected data field	Baseline value for affected data field
Past tobacco smoking (1249)	(1 : Smoked on most or all days) (4 : I have never smoked)	Light smokers, at least 100 smokes in lifetime (2644) Light smokers, at least 100 smokes in lifetime (2644)	(1 : yes) (0 : no)
Past tobacco smoking (1249)	(2 : Smoked occasionally—(3 : Just tried once or twice)—(4 : I have never smoked)	Type of tobacco previously smoked (2877)	Not applicable
Adopted as a child (1767)	(0 : No)	Adopted mother still alive (3942)	Not applicable
Adopted mother still alive (3942)	(0 : No)	Mother's age (1845)	Not applicable
Adopted mother still alive (3942)	(1 : Yes)	Mother's age at death (3326)	Not applicable
Mother still alive (1835)	(0 : No)	Mother's age (1845)	Not applicable
Mother still alive (1835)	(1 : Yes)	Mother's age at death (3326)	Not applicable
Adopted as a child (1767)	(0 : No)	Mother's age at death (3326)	Not applicable
Adopted father still alive (3912)	(0 : No)	Adopted father still alive (3912)	Not applicable
Adopted father still alive (3912)	(1 : Yes)	Father's age (2946)	Not applicable
Father still alive (1797)	(0 : No)	Father's age at death (1807)	Not applicable
Father still alive (1797)	(1 : Yes)	Father's age (2946)	Not applicable
Job involves shift work (826)	(1 : Never/rarely)	Father's age at death (1807)	Not applicable
Frequency of travelling from home to job workplace (777)	NaN	Job involves night shift work (3426)	(1 : Never/rarely)
Frequency of travelling from home to job workplace (777)	NaN	Distance between home and job workplace (796)	0
Frequency of travelling from home to job workplace (777)	NaN	Transport type for commuting to job workplace (6143)	Not applicable
Adopted as a child (1767)	(0 : No)	Illnesses of adopted father (20112)	Not applicable
Adopted as a child (1767)	(0 : No)	Illnesses of adopted mother (20113)	Not applicable
Adopted as a child (1767)	(0 : No)	Illnesses of adopted siblings (20114)	Not applicable
Bipolar disorder status (20122)	NaN	Bipolar disorder status (20122)	Not collected
Single episode of probable major depression (20123)	NaN	Single episode of probable major depression (20123)	Not collected
Probable recurrent major depression (moderate) (20124)	NaN	Probable recurrent major depression (moderate) (20124)	Not collected
Probable recurrent major depression (severe) (20125)	NaN	Probable recurrent major depression (severe) (20125)	Not collected
Bipolar and major depression status (20126)	NaN	Bipolar and major depression status (20126)	Not collected
Myopia diagnosis (20262)	NaN	Myopia diagnosis (20262)	Not collected
Country of birth (UK/elsewhere) (1647)	(6 : Elsewhere)	Year immigrated to UK (United Kingdom) (3659)	Not applicable
Adopted as a child (1767)	(0 : No)	Number of adopted brothers (3972)	Not applicable

Table 5 – continued from previous page

Conditioning data field	Conditioning triggering values	Affected data field	Baseline value for affected data field
Adopted as a child (1767)	(0 : No)	Number of adopted sisters (3982)	Not applicable
Ever depressed for a whole week (4598)	(0 : No)	Longest period of depression (4609)	Not applicable
Ever depressed for a whole week (4598)	(0 : No)	Number of depression episodes (4620)	Not applicable
Adopted as a child (1767)	(1 : Yes)	Number of older siblings (5057)	Not applicable
Ever unenthusiastic/disinterested for a whole week (4631)	(0 : No)	Ever unenthusiastic/disinterested for a whole week (5375)	Not applicable
Ever unenthusiastic/disinterested for a whole week (4631)	(0 : No)	Number of unenthusiastic/disinterested episodes (5386)	Not applicable
Past tobacco smoking (1249)	(4 : I have never smoked)	Pack years of smoking (20161)	0
Past tobacco smoking (1249)	(4 : I have never smoked)	Pack years adult smoking as proportion of life span exposed to smoking (20162)	0
Microalbumin in urine result flag (30505)	(<6.7; "below 6.7 mg")	Microalbumin in urine (30500)	0

Table 6: UK Biobank (UKB) question answers replaced by missing values.

UKB response identifier	UBK description
-1	Question not asked due to previous answers
-3	Prefer not to answer
-7	None of the above
-11	Do not know (group 1)
-21	Do not know (group 2)
-1	Do not know
-1	Participant skipped/abandoned
-17	None of the above (group 1)
-23	Prefer not to answer (group 2)
-27	None of the above (group 2)
-5	Not sure
-13	Prefer not to answer (group 1)
-10	Less than once a week

Table 7: Average percentage of missing data for each UK Biobank categories after data engineering .

Category Id	Category description	Average % missing
100009	Body composition by impedance - Anthropometry - Physical measures - Assessment Centre	2.05
100010	Body size measures - Anthropometry - Physical measures - Assessment Centre	14.72
100011	Assessment centre - Physical measures - Blood pressure	34.42
100014	Autorefraction - Eye measures - Physical measures - Assessment Centre	80.01
100015	Intraocular pressure - Eye measures - Physical measures - Assessment Centre	77.70
100017	Visual acuity - Eye measures - Physical measures - Assessment Centre	77.31
100019	Hand grip strength - Physical measures - Assessment Centre	0.67
100027	Fluid intelligence / reasoning - Cognitive function - Assessment Centre	78.99
100030	Pairs matching - Cognitive function - Assessment Centre	0.93
100031	Prospective memory - Cognitive function - Assessment Centre	65.88
100032	Reaction time - Cognitive function - Assessment Centre	1.49
100034	Family history - Touchscreen - Assessment Centre	7.04
100052	Diet - Lifestyle and environment - Touchscreen - Assessment Centre	4.49
100053	Electronic device use - Lifestyle and environment - Touchscreen - Assessment Centre	11.50
100057	Sleep - Lifestyle and environment - Touchscreen - Assessment Centre	3.10
100058	Smoking - Lifestyle and environment - Touchscreen - Assessment Centre	10.06
100060	Mental health - Psychosocial factors - Touchscreen - Assessment Centre	33.86
100063	Education - Sociodemographics - Touchscreen - Assessment Centre	5.62
100064	Employment - Sociodemographics - Touchscreen - Assessment Centre	7.12
100065	Ethnicity - Sociodemographics - Touchscreen - Assessment Centre	0.55
100066	Household - Sociodemographics - Touchscreen - Assessment Centre	24.60
100067	Other sociodemographic factors - Sociodemographics - Touchscreen - Assessment Centre	16.75
100081	Blood count - Blood assays - Biological samples	5.32
100083	Urine assays - Biological samples	4.09
100099	Eye surgery/complications - Eye measures - Physical measures - Assessment Centre	90.12
114	Residential air pollution - Local environment - Additional exposures	4.72
17518	Blood biochemistry - Blood assays - Biological samples	15.79
54	MET Scores - Physical activity - Lifestyle and environment - Touchscreen - Assessment Centre	19.70
76	Indices of Multiple Deprivation - Baseline characteristics - Population characteristics	13.90

n.b. The permutation feature importance assesses the c-statistic change in the test data; iteratively the values of each variables were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance used as an estimate of variable contribution to the model's predictive potential.

Table 9: Feature importance of top 20 variables identified by the Elastic Net model for "w T2DM" group.

n.b. The permutation feature importance assesses the c-statistic change in the test data; iteratively the values of each variables were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance used as an estimate of variable contribution to the model's predictive potential.

Table 10: Feature importance of top 20 variables identified by the Elastic Net model for "w T2DM&CVD" group.

n.b. The permutation feature importance assesses the c-statistic change in the test data; iteratively the values of each variables were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance used as an estimate of variable contribution to the model's predictive potential.

Table 11: The number of variables used for training a multivariable elastic net algorithm and the number of CVD events during a 10-year follow-up period stratified by training and testing samples.

Group	Outcome	Sample size	No. events train (%)	No. events test (%)	No. variables

n.b. Individuals are stratified as followed "wo T2DM/CVD": participants without T2DM or CVD at baseline, "w T2DM": participants with diabetes at baseline, "w T2DM&CVD": participants with T2DM at baseline and a history of CVD. The analysed outcomes include cardiovascular disease including heart failure (HF) and/or atrial fibrillation (AF) (CVD+), cardiovascular disease (CVD), coronary heart disease (CHD), HF, AF, and Ischaemic Stroke. Train discrimination (c-statistic) is based on 80% of train set of the total data used for this study, while test discrimination is calculated using remaining 20% of the total dataset. Point estimates are presented alongside 95% CI.

1.4 Figures

Figure 1: Overview of the study design pipeline.

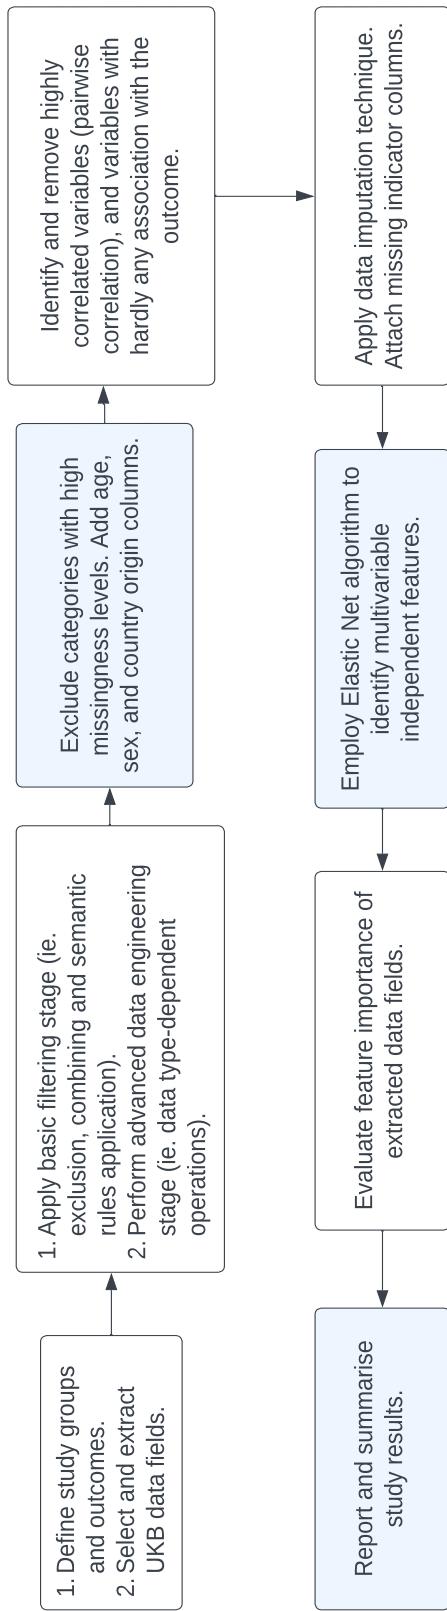

Figure 2: Flow diagram of the initial filtering and standardization step.

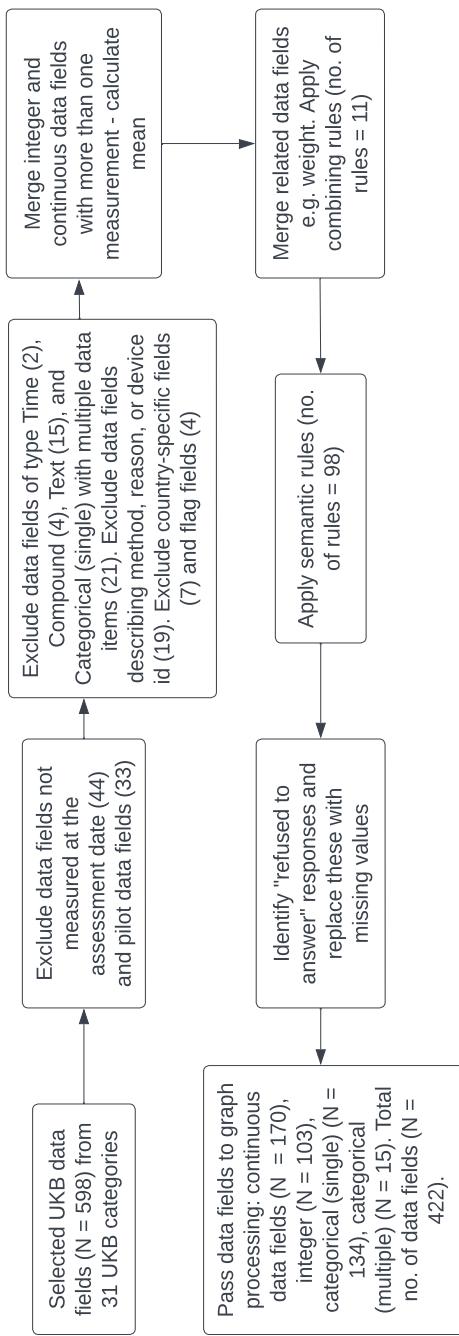

Figure 3: Flow diagram of data type-specific transformation step.

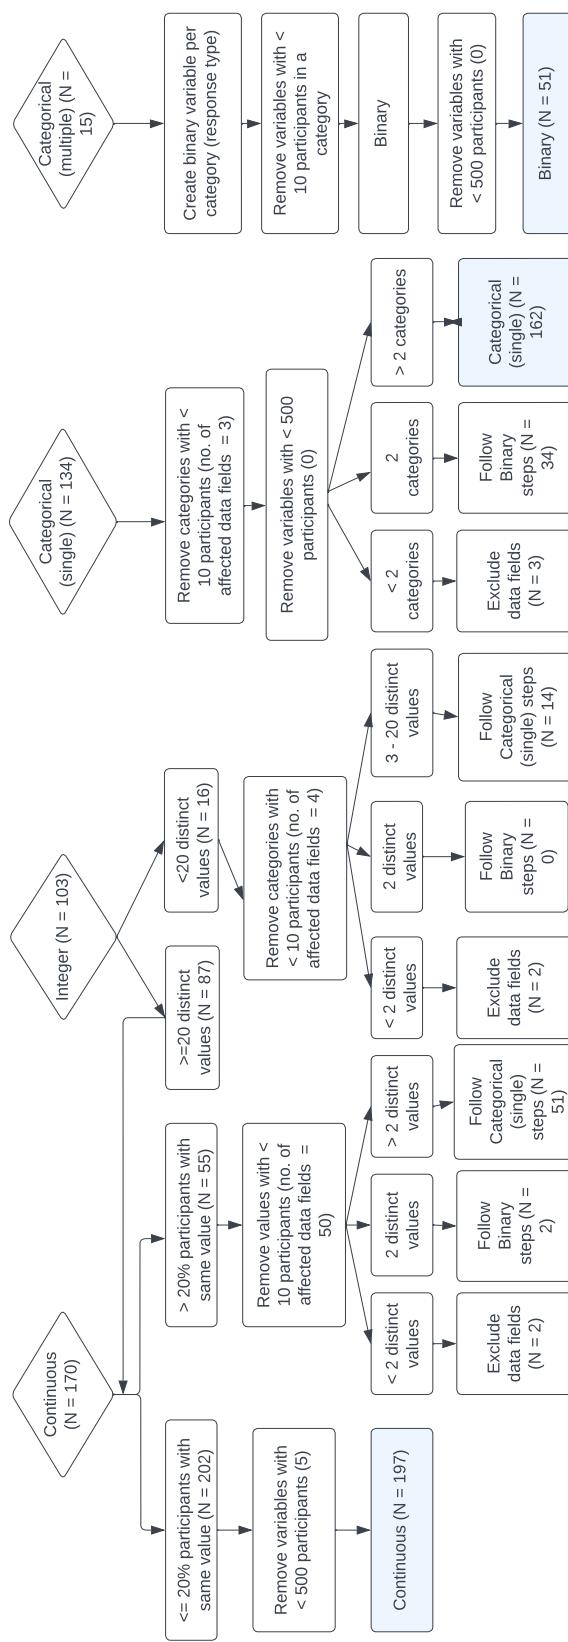

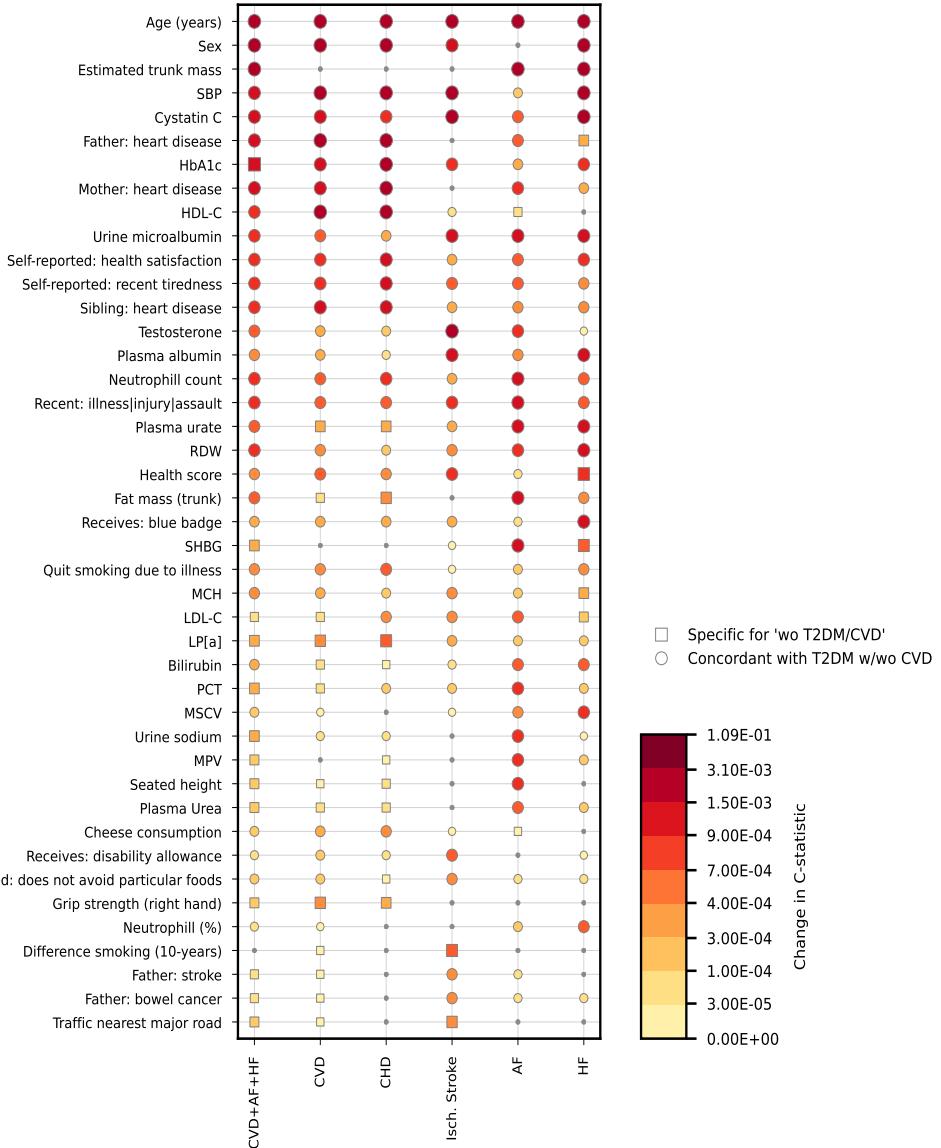

Figure 4: The contribution of the top features to the prediction of six facets of CVD for "wo T2DM/CVD" group.

N. B. The y-axis presents the union of the top 20 features based on the c-statistic change for each of the six CVD outcomes, features in violet originate from the NMR UKB category. Plot markers (e.g. triangle, square) highlight the differences in identified features between groups. The permuted feature importance reflects the c-statistic change based on the test data; iteratively the values of each variable were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance was used as an estimate of a variable contribution to the model's predictive potential. Abbreviations: glycated haemoglobin (HbA1c), high-density lipoprotein cholesterol (HDL-C), red blood cell distribution width (RDW), systolic blood pressure (SBP), sex hormone-binding globulin (SHBG), mean corpuscular haemoglobin (MCH), lipoprotein A (LP[a]), low-density lipoprotein cholesterol (LDL-C), platelet crit (PCT), mean platelet (thrombocyte) volume (MPV), mean spherulite cell volume (MSCV).

Figure 5: The contribution of the top 60 features to the prediction of six facets of CVD for "w T2DM" group.

N. B. The y-axis presents the union of the top 20 features (limited to maximum 60 features) based on the c-statistic change for each of the six CVD outcomes. Plot markers (e.g. triangle, square) highlight the differences in identified features between groups. The permuted feature importance reflects the c-statistic change based on the test data; iteratively the values of each variable were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance was used as an estimate of a variable contribution to the model's predictive potential. Abbreviations: glycated haemoglobin (HbA1c), systolic blood pressure (SBP), red blood cell distribution width (RDW), high light scatter reticulocyte count (HLR), sex hormone-binding globulin (SHBG), Qualifications (O levels / General Certificate of Secondary Education or equivalent) (O-levels/GCSEs), high-density lipoprotein cholesterol (HDL-C), diastolic blood pressure (DBP), lipoprotein A (LP[a]).

Figure 6: The contribution of the top 60 features to the prediction of six facets of CVD for "w T2DM&CVD" group.

N. B. The y-axis presents the union of the top 20 features (limited to maximum 60 features) based on the c-statistic change for each of the six CVD outcomes. Plot markers (e.g. triangle, square) highlight the differences in identified features between groups. The permuted feature importance reflects the c-statistic change based on the test data; iteratively the values of each variable were randomly assigned to an individual after which the c-statistic was re-estimated with these permuted data and the difference in performance was used as an estimate of a variable contribution to the model's predictive potential. Abbreviations: red blood cell distribution width (RDW), alanine aminotransferase (ALT), low-density lipoprotein cholesterol (LDL-C), gamma glutamyltransferase (GGT), systolic blood pressure (SBP), qualifications (CSEs or equivalent) (CSE-equivalent), glycated haemoglobin (HbA1c), c-reactive protein (CRP), platelet crit (PCT), qualifications (NVQ or HND or HNC or equivalent) (NVQ/HND/HNC-equivalent).
