19	Abstract

Background: Mental health recovery is associated with healthy sleep, and disturbances of both, areas represent an increasing public health issue worldwide, particularly in Latin America. Among multiple determinants affecting sleep health, individual's socioeconomic status (SES) is the most ignored and underestimated through

- literature. No systematic review on the relation between SES and sleep health has been previously conducted in
   Latin America. *Methods:* PRISMA guidelines were used.
- 25 *Results:* Twenty cross-sectional studies were selected. 80,0% (n=16) were performed in Brazil, 10,0% (n=2) in Peru, 5,0% (n=1) in Chile, and 5,0% (n=1) were multicentric (11 countries). The combined total number of 26 participants were N=128455, being 3,7% (n= 4693) children, 16,0% (n= 20586) adolescents and 80,3% 27 (n=103176) adults. Higher SES was associated with lower sleep duration. Lower SES was associated with a 28 29 decrease in sleep quality. Excessive Daytime Sleepiness (EDS) was significantly more prevalent in individuals with lower family income and less education. Sleep bruxism was associated with higher education and lower 30 31 SES was associated with more sleep bruxism. A meta-analysis of random effects model showed that pooled prevalence of sleep disturbances was 27.32 % (95 % CI 21.71–33.75) with high heterogeneity ( $I^2 = 100$  %). 32 Pooled prevalence decreased with high education (OR 0.83; 95%CI [0.75-0.91];  $I^2 = 79\%$ ), while it increased 33 by low income (OR 1.26; 95% CI [1.12-1.42];  $I^2 = 59\%$ ), unemployment (OR 2.84; 95% CI [2.14-3.76];  $I^2 = 0\%$ ) 34 35 or being housewife (OR 1.72; 95%CI [1.19-2.48];  $I^2=55.4\%$ ).
- *Discussion:* Gradient of health disparity existing for some diseases like cardiovascular illness, seems the same for sleep disturbances regardless of world region. Therefore, sleep disturbances management should be address in a multidimensional approach with a significant investment of government in targeted public health program, to reduce sleep disparities and support research before the situation become uncontrollable.

44

#### **1- INTRODUCTION** 45

Promoting recovery in mental health is an ongoing project which never ends, because mental health is a complex 46 public health outcome requiring multidimensional interventions at the economic level, the populational level 47 48 and societal level [1,2]. Mental health is also highly dependent of sleep which has a recognized impact on 49 several brains functions [3] and global health status as well as stress [4]. In addition, sleep has a significant 50 influence on mental health due to its relationship with people's socioeconomic status (SES) and its connection with multiple biological systems involved in neurological disorders such as anxiety [1,5–10]. That means in 51 52 others words that, sleep disturbances are mental disorders resulting from complex socioecological and economic 53 interactions between brain, society where we live, global health and SES [7,11,12]. Thus, sleep health 54 inequalities represents a mental health outcome similar to public health issues previously reported for 55 cardiovascular, mental health and metabolic diseases [11]. Empirical literature in western countries seems 56 validated the hypothesis stating that, low SES individuals reported more sleep disturbances than high SES 57 people [13–18]. Similar evidence exists in Asia [19,20] and Oceania [21,22]. Thus, sleep health disparity could 58 be public health issues in other regions, such as Africa and Latin America. Few studies documented sleep health 59 disparities in South and Central America due to a wide range of determinants such as employment, income, 60 education, occupation and social position [11,23-25]. A comprehensive evaluation of public health literature 51 related to Latin America showed that no previous systematic review has investigated the relationship between 62 SES and sleep health in this region. It's important to analyze if trends related to the influence of SES 63 determinants of mental health on sleep health observed in western countries are following the same patterns in 64 Latin America. The goals of this systematic review are to 1) document the socioeconomic determinants of sleep health in Latin America and 2) promote the mental health recovery related to a good sleep health. 65

66

67

#### 2- METHODS 58

2.1- Literature search 59

Relevant peer review studies included in this systematic review were identified by searching the following databases: Web of Science, Scopus, PubMed/Medline and Ovid, restricted on a period between January 1990 and May 2023. A combination of terms "socioeconomic", "socio-economic", "social position", "social class", 'socioeconomic position', "determinant\*", "indicators\*", "markers\*", "health inequalities", "health inequities", "sleep", 'sleep disorders', 'sleep disturbances'', 'sleep complains'', "sleep outcome", "sleep health", "south america\*", "southern america\*", "central america\*", "latin america" was used. All included articles were identified following the PRISMA guidelines detailed in Figure 1 [25].

77

78

Figure 1. PRISMA flowchart of study selection process

### 79 2.2- Selection of evidence and data extraction

Two reviewers (*FAES*, *SZ*) independently reviewed the titles and abstracts of the studies identified by the search strategy and determined eligibility for inclusion, while disagreements were resolved by consensus with a third external reviewer. For studies that passed the initial screening, the entire text was collected and the screening process was repeated by the same co-authors to conclude with the final articles included, validated by the third reviewer. Then, four reviewers (FTS, RQR, MC, FAES) extracted from each report the following studies characteristics: population, % women, age, sample size, SES measures, relevant statistics, interaction or mediation, sleep measures, conclusions/main effects, statistical methods and results significance.

87

### 88 2.3- Inclusion and exclusion criteria

89 Empirical studies were defined as studies of any design (cross-sectional, retrospective or longitudinal) assessing humans of any gender, race/ethnicity and age from the general population of any country from Latin America. 90 The article should include an objective or a subjective measure of SES, such as income, educational level, 91 wealth, profession/occupation, employment status, perceived SES or self-reported SES. Proxy measures of SES, 92 such as neighborhood and social class, were also included. For studies involving children and adolescents, 93 94 perceived family SES measures, such as parental education, parental occupation or annual household income were utilized. Studies were excluded based on the following criteria: 1) They were interventional trials, any 95 96 type of reviews (narrative, overview, systematic, umbrella, meta-analyses), case series, case reports, conference series or any writing without original research (editorial, commentary, letter to editors), 2) articles did not 97 provide statistical significance in cases where either SES or sleep were evaluated as covariates or mediators, 3) 98 99 the full text was not accessible, 4) authors/researchers recruited participants with medical conditions at the beginning of study (for example people with medications including sleep pills, people with cancers, people with 00 01 neurodegenerative diseases, etc....) and 5) articles were not written in English, French, Portuguese and Spanish (languages of authors). 02

03

#### 04 **2.4-** Quality rating of studies

The National Institute of Health's (NIH) Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies was used to rate the quality of included studies [26]. This quality rating's tool analyzed fourteen quality criteria asking an equal number of questions about study objectives, population, exposures, outcomes, follow-up rates, and statistical analysis. SES was considered the exposure variable and sleep measures were the outcome variable, respectively. Overall quality ratings (**Table 2**) were calculated by taking the proportion of positive rating for the sum of applicable criteria. Studies with < 50% positive rating were judged as poor quality,  $\geq 65\%$  as good quality, and the rest as fair quality [26].

12

13

#### 14 2.5- Study outcomes

The primary outcomes were related to the prevalence of sleep disturbances in Latin America and the difference in sleep length between men and women. The secondary outcomes aimed to explore how SES influences the prevalence of sleep disturbance in Latin America. This exploration was conducted through analyzing education, income, employment status, and perceived SES, as long as they were reported by at least two independent studies.

20

#### 21 **2.6- Data analysis**

Meta-analysis was performed using the meta package on R with RStudio interface (Version 4.1.3, R Core Team,
2022) to analyze the collected data.

In each study, the prevalence of sleeping disturbances in Latin America was obtained. Studies did not report the prevalence are excluded. The random effects model was used with the logit transformation for obtaining the pooled results, because it produces more conservative results than fixed-effects models regardless of heterogenicity scores [27]. The pooled prevalence estimates of sleeping disturbances in Latin America was presented as a percentage with 95% confidence intervals (CIs) using a forest plot. Also, a subgroup analysis was conducted for different sleep issues, cities, study's quality and age group to assess the contribution of each study to overall heterogeneity in the prevalence of sleep disturbance.

To measure the relationship between SES and sleeping disturbances, we extracted from the selected publications the adjusted odds ratio (aOR) with 95% CIs. Their standard errors were calculated from the respective CIs. The value from each study and the corresponding standard error were transformed into their natural logarithms to stabilize the variances and to normalize the distribution. The pooled OR (and 95%CI) was estimated using a DeirSimonian-Laird random effect model. In situations in which a study reported effect estimates for independent subgroups, the subgroups were treated as individual studies in the meta-analysis.

The test of the overall effect was assessed by using Z-statistics at p<0.05. The heterogeneity among the included studies was assessed using Cochran's Q test and  $I^2$  statistics. The thresholds of 25%, 50%, and 75% were used to indicate low, moderate, and high heterogeneity, respectively [28, 29]. A funnel plot based on Egger's

regression test was used to evaluate the publication bias [30]. In all analysis, a *p*-value less than 0.05 was considered statistically significant.

42

### 43 **3-** <u>**RESULTS**</u>

#### 44 3.1- Characteristics of included articles

45 Twenty articles were included [31–50] in the final sample, all cross-sectional studies and available in **Table 1**. Among these studies, 80,0% (n=16) were performed in Brazil [31–33, 35, 37, 38, 41–50], 10,0% (n=2) in Peru 46 47 [39, 40], 5,0% (n=1) in Chile [34], and 5,0% (n=1) were multicentric (11 countries) [36]. The combined total 48 number of participants were N=128455, being 3,7% (n= 4693) children, 16,0% (n= 20586) adolescents [38, 39, 41, 42, 45] and 80,3% (n=103176) adults [31-37, 39, 40, 46-50]. The smallest sample size was n=851 [43] and 49 the largest was n=60202 [49]. The socioeconomic indicators used were income (monthly personal income, 50 monthly family income, per capita income, annual household income) [31-35, 37, 38, 41, 43-47], wealth/assets 51 52 [37, 39, 40, 49, 50], number of residents in the household [46], employment status/occupation [31, 32, 34, 35, 53 37–39, 46, 47, 50], accessed healthcare system [37] and composite indices [42]. The sleep variables used were 54 excessive daytime sleepiness [32, 40, 49], sleep duration [37–39, 41, 44–46, 50], sleep quality/sleep disturbance 55 [33, 34, 36, 38, 44, 47, 49], insomnia [31, 36], obstructive sleep apnea (OSA)/sleep-disordered breathing (SDB) 56 symptoms [35, 40] and bruxism [42, 43, 48]. Majority of articles were of poor quality (55%) and detailed 57 qualitative evaluation is available in Table 2.

#### 3.2- Descriptive synthesis of articles

Quantitative analyses are presented in the results section. Presented below is a descriptive analysis, which

provides a deeper examination of the overall findings that were not considered in the quantitative analysis. Table

1 presents details of the individual studies included in the descriptive analysis.

Sleep duration:

- Seven cross-sectional studies examined the relation between socioeconomic status (SES) and sleep duration [37–39, 41, 44, 46, 50]. One of these was conducted with children (from 3 to 48 months old) [44], two studied adolescents (12 to 19 years old) [38, 41], three involved adults [37, 46, 50] and one encompassed both adolescents and adults [39].
- Overall, a higher SES was associated with shorter sleep duration. Specifically, highest level of education [37– 39, 41, 46], being employed [37–39, 46], higher income [38, 39, 41, 46] and living with more residents [46] were associated with shorter sleep duration in samples of adults and adolescents. In addition, long sleep was more prevalent among housewives [37], adolescents with black maternal skin color [41] and whose mothers had lower schooling [41].
- In contrast, the poorest wealth index and being unemployed or not studying were associated with lower sleep percentage in another study with adults[50]. One study did not find consistent associations between sleep duration and maternal education or family income in children [44]. The overall quality of the selected studies was good for three studies [38, 41, 41] and fair for four studies [37, 39, 44].
- 94

#### 95 Sleep quality/sleep disturbance:

Eight cross-sectional studies assessed the relationship between sleep quality or disturbance and SES [33, 34, 36, 38, 44, 45, 47, 49]. One of these studies was conducted with infants (from 3 to 48 months) [44] two with students (14 to 19 years old) [38, 45] and the others with adults [33, 33, 47, 49]. One study focused only on adult women [36]. The overall quality of the studies selected was good for three studies [36, 38, 45], fair for three studies [33, 34, 47] and poor for one study [49].

- Globally, lower SES was associated with diminished sleep quality. Specifically, low income [33, 38] and unemployment [34, 47] were associated with impaired sleep quality. Two studies indicated a higher prevalence of sleep disturbance in women [34, 47]. More educated adults had significantly less sleep disturbance [33, 36, 49]. In contrast, one study found that higher maternal education was associated with lower quality of sleep in students [45], but this association was not found in infants in another study [44]. Additionally, psychiatric
- comorbidities [33, 34], alcohol and drug consumption [34, 36] were also associated with sleep disturbance.

07

#### 08 Insomnia:

Concerning insomnia, two cross-sectional studies assessed its relationship with SES [31, 36]. One study evaluated only women [36] and one study assessed adults in general[31]. The overall quality of the two studies was good.

In both of the aforementioned studies, insomnia was independently associated with individuals with less education [31, 36]. Moreover, alcohol and drug consumption was also associated with insomnia, according to another study [36].

15

#### 16 Excessive daytime sleepiness:

17 Three cross-sectional studies approached the association between excessive daytime sleepiness and SES [32,

40, 49]. All studies assessed adults. The overall quality of the studies selected was good for one study [32], fair

for another study [40] and poor for the third study [49].

Largely, excessive daytime sleepiness was associated with lower SES in one the studies [40]. Additionally, it

21 was also significantly more prevalent in individuals with lower family income [32] and less education [49].

22 23

25

#### 24 Obstructive sleep apnea (OSA) / Sleep-disordered breathing (SDB) symptoms:

Concerning OSA/SDB, two cross-sectional studies assessed their relationship with SES [35, 40]. Both studies evaluated adults in the general population. The overall quality was good in one study [35] and fair for the other study [40].

In one study, lower SES was associated with less frequent snoring. However, no significant association was found between SES and observed apneas [35]. The other study did not find any association between SES and OSA [40].

- 32
- 33
- 34 Bruxism:

Three cross-sectional studies assessed the relation between SES and bruxism [42, 43, 48]. One of the studies was conducted with infants (ages 6-12 years)[43], one with adolescents (aged 13-15 years) [42] and the last one with adults [48]. The overall quality was good in two studies [42, 43] and fair in one study [48].

Among these three studies, two studies reported that sleep bruxism was independently associated with higher SES, including higher education[42, 48]. However, the other study, conducted by Mota-Veloso *et al.* [43], found out that SES had a significant indirect effect on bruxism via sucking habits (finger sucking, nails or other objects bite) and that lower SES was associated with more sleep bruxism [43].

42

45

# 43 44 3.3- Prevalence of sleep disturbances in Latin America

Based on our selection criteria, eighteen studies [31–40, 42–49] were eligible. Where results in the same article were reported for different sleep disturbance types separately, they were entered into the analysis as separate studies. Therefore, a total of 18 papers including 28 studies were included in the final meta-analysis which is shown in **Fig 2.A**.

50 The overall pooled prevalence for sleep disturbance in Latin America was 27.32 % (95 % CI 21.71–33.75,  $I^2 =$ 

51 100 %) (**Fig 2.A**). To decide whether to include all of the articles examining sleep disturbances or not, a 52 publication bias chart was created. The results showed that publication bias was not significant (p = 0.059) (**Fig** 53 **3**).

54 We divided eighteen papers into seven categories according to different types of sleep disturbances. Subgroup analysis was manipulated based on seven categories (Fig 4). The highest prevalence was for insomnia, with 55 56 39.52 % (95 % CI 31.79–47.82; p < 0.01), and the lowest prevalence was for EDS, with 15.52 % (95 % CI 11.85–20.07; p < 0.01). The overall pooled prevalence for sleep disturbance was 37.22 % (95 % CI 27.73– 57 58 47.82; p = 0) across eight articles [33, 34, 36, 38, 44, 45, 47, 49], for OSA/SDB was 31.32 % (95 % CI 28.77– 59 34.00; p = 0.11) across two articles [35, 40] and for bruxism was 16.60 % (95 % CI 8.83–29.04; p < 0.01) across 60 three articles [42, 43, 48]. The overall pooled prevalence for short sleep duration was 23.09 % (95 % CI 8.98-47.75; p =0) across four articles [37–39, 46], and for long sleep duration was 21.67 % (95 % CI 15.95–28.75; p 51 < 0.01) across three articles [37, 39, 46]. 62

- 53
- 64

### 55 **3.4-** Sleep length in Latin America

A total of two articles [41, 50] reported the sleep length (fig 2.B). Where results were reported for men and women separately, they were entered into the analysis as separate studies. In the pooled analysis, sleep length was significantly higher in men with sleep disturbances than in women with sleep disturbances with a standardized mean of 0.40 hours (95% CI: 0.34-0.47; p = 0.11;  $I^2 = 100\%$ ).

#### 3.5-Subgroup analysis 328

327

- Because of significant heterogeneity across the included studies, a subgroup analysis was performed by region 329 (cities), age groups and study quality, in relation to principal outcome variable. The analysis revealed that the 330 331 prevalence of sleep disturbances was highest in Brazil 28.52 (95 % CI 22.38-35.57) than Peru 15.91 (95 % CI 6.17-35.27). Also, the pooled prevalence of sleep disturbances among infant 56.52 (95 % CI 54.11-58.89) was 332 333 greater than adolescents 27.11 (95 % CI 16.55-41.09) and adults 24.24 (95 % CI 18.93-30.48) (Table 3).
- Table 3: Subgroup analyses for the prevalence of sleep disturbances in Latin America 334

335 336

#### 337 3.6-Risk factors

338

342

343

Meta-analysis was possible for sleep disturbances prevalence with three SES factors (Education, income and 339 employment status). 340 341

### 3.6.1-Education and Sleep disturbances

Eight studies [31, 33, 36, 37, 39, 45, 48, 49] evaluated the association between education and prevalence of 344 sleep disturbances as shown in Fig 5.A. There was found no association between low education and prevalent 345 sleep disturbances, with a pooled OR of 1.42 (95%CI [0.87-2.29]; p = <0.01). However, the meta-analysis 346 showed that the high educated population had a lower prevalence of sleep disturbances (OR 0.83; 95%CI [0.69-347 0.99]; p = < 0.01), with a high heterogeneity between studies (I<sup>2</sup>= 79%). 348

medRxiv preprint doi: https://doi.org/10.1101/2023.06.02.23290915; this version posted November 13, 2023. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in perpetuity.
Separating the education analyses do y quality of a studies Ndidonot preveal rai significant subgroup effect for sleep disturbances prevalence (*p*=0.70; **Fig 6.A**). Similarly, when the education analyses were separated by cities, no significant subgroup effect for the prevalence of sleep disturbances was observed (*p*=0.70; **Fig 6.B**).

352

354

**353 3.6.2-Income and Sleep disturbances** 

Six studies [32, 33, 35, 38, 39, 46] considered income as a risk factor of sleep disturbances in Latin America. The meta-analysis revealed a significant relationship between low income and the prevalence of sleep disturbances (OR 1.26; 95%CI [1.12-1.42]; p=0.09), with moderate heterogeneity between studies (I<sup>2</sup>= 59%). However, it did not show a significant association between middle income (OR 1.07; 95%CI [0.78-1.46]; p=<0.01) or high income (OR 0.76; 95%CI [0.34-1.32]; p=<0.01) and prevalence of sleep disturbances (**Fig 5.B**).

361

363

362 **3.6.3-***Work and Sleep disturbances* 

Data on the relationship between work and sleep disturbances are shown in **Fig 5.C.** The meta-analysis showed a significant relationship between no working and the prevalence of sleep disturbances (OR 2.84; 95%CI [2.14-3.76]; *p*=0.09) with no heterogeneity between studies (I<sup>2</sup>= 0%). Similarly, in the pooled analysis, being housewife was associated with high prevalence of sleep disturbances (OR 1.72; 95%CI [1.19-2.48]; *p*=0.13), exhibiting moderate heterogeneity across studies (I<sup>2</sup>= 55%). 369

#### 23 **4- DISCUSSION**

#### 24 4.1- Detailed summary of findings

25 The most used determinants were income (monthly personal income, monthly family income, per capita income, 26 annual household income), wealth/assets, number of residents in the household, employment status/occupation, 27 accessed healthcare system and composite indices. The sleep outcomes analyzed were excessive daytime sleepiness (EDS), sleep duration, sleep quality/sleep disturbance, insomnia, obstructive sleep apnea 28 29 (OSA)/sleep-disordered breathing (SDB) symptoms and bruxism. Higher SES was associated with lower sleep 30 duration. Lower SES was associated with a decrease in sleep quality. EDS was significantly more prevalent in 31 individuals with lower family income and less education. Sleep bruxism was associated with higher education 32 and lower SES was associated with more sleep bruxism. Among the 20 included articles, 12 were rated as fair 33 or poor in study quality. Therefore, a meta-analysis was performed to estimate the prevalence of sleep 34 disturbances in Latin America and the main SES risk factors that could be associated with it. The pooled prevalence using a meta-analysis of the random effects model was 27.32 % (95 % CI 21.71–33.75), with high 35 heterogeneity ( $I^2 = 100$  %). The meta-analysis showed that the prevalence of sleep disturbances decreased with 36

high education (OR 0.83; 95%CI [0.75-0.91]; I<sup>2</sup>= 79%), while it increased with low income (OR 1.26; 95%CI [1.12-1.42]; I<sup>2</sup>= 59%), unemployment (OR 2.84; 95%CI [2.14-3.76]; I<sup>2</sup>= 0%) and being housewife (OR 1.72; 95%CI [1.19-2.48]; I<sup>2</sup>=55.4%).

40

#### 41 4.2- Relationship with public health literature

Epidemiologic data continues to increase the literature about the influence of sleep on general population's 42 health status. Sleep plays a vital role in several body functions as well as health disparities. Nowadays, scientific 43 44 community is still investigating external and environmental factors affecting sleep mechanisms, but there are still a lot unknown. Based on current findings, it can be hypothesized that sleep disturbances are associated with 45 46 socioeconomic status liked suggested many other studies [17, 51-58]. The fact is, gradient of health disparity 47 existing for some diseases like cardiovascular illness, seems the same for sleep. Regardless of world region where investigation is made, sleep disparities are observed because our findings on Latin America supports 48 49 previous results [17, 51–58]. Our findings are coherent with previous studies elsewhere than Latin America and 50 they are additional arguments in favor of the establishment of a more efficient worldwide program framing sleep 51 health management.

- 52
- 53

### 54 4.3- The necessity of a multidimensional sleep management

55 The management of sleep disturbances should be addressed through a multidimensional approach. The majority of studies used to focus on biological and psychological factors influencing sleep while it was only recently that 56 57 SES was recognized as major determinant of sleep. Recent epidemiological studies performed outside Latin 58 America in different public health contexts, associated sleep with stress [4], work conditions [8], environment 59 [59], employment [17, 60, 61] and revealed latent interactions existing between government policy and public health strategies [22, 55, 62-64]. Obviously, a government's economic policy influences funding of public health 60 51 programs. Similarly, SES influences directly health status regardless disease assessed through individual's living 62 conditions and their resulting behavioral risk factors and stress. Knowing that sleep disparities can be measured

objectively and quantitatively [6, 7, 50], our suggestion for governments is to invest as soon as possible in preventive management programs of sleep disturbances; before they become uncontrollable. It was already documented how expensive for economy were absenteeism and presenteeism due to sleep disturbances [65, 66], but diverse governments didn't move forward yet with strong regulations to reduce these important losses [67, 68].

58 In this meta-analysis, there is an unequal distribution of research, with 80% of studies originating from Brazil (**Table 1**). Even if Brazil is representative of Latin American populations, its public health's context regarding 59 70 sleep management is not necessarily identical for its neighbors. More research should be performed in other 71 Latin American countries to obtain an accurate overview of sleep disparities in this continent. Our suggestion 72 for scientists, is to not forget that cross-sectionals studies are often used to understand determinants of health 73 and establish preliminary evidence [69]; but are useless when it is necessary to consider correlation between 74 theoretical determinant and health outcome. This first meta-analysis on sleep determinants in Latin America, 75 enlighten the high quality of cross-sectional studies published but also the lack of systematic review and 76 longitudinal studies. To support public health strategies, randomized controlled trial and longitudinal studies are 77 required [69].
