Correlation between umbilical cord torsion and Doppler 1 parameters of umbilical artery: a single-center retrospective 2 case-control study 3

4

5 Abstract

6 Objective: To explore the correlation between umbilical cord torsion and the changes of umbilical artery Doppler 7

parameters, to provide valuable information for prenatal ultrasound screening of umbilical cord torsion, and to 8 explore the possible mechanism of umbilical artery Doppler parameters changes during umbilical cord torsion.

9 Method: The subjects were 962 pregnant women who were discharged from our hospital from January 2015 to

10 November 2021 and were eligible for inclusion (415 in the case group and 547 in the control group). The

measurement data of umbilical artery Doppler parameters (PSV, S/D, RI, PI) were collected from 21 to 40 weeks of 11

12 gestation, and the differences among the above parameters were statistically analyzed.

13 Results: The peak systolic velocity (PSV) of umbilical artery is positively correlated with gestational age, while the

14 Doppler resistance parameters (S/D, RI, PI) of umbilical artery are negatively correlated with gestational age. The

15 mean values of umbilical artery Doppler parameters (PSV, S/D, RI, PI) in the case group were significantly lower 16 than those in the control group of the same pregnancy age (P < 0.05).

17 Conclusion: The decrease of Doppler parameters of umbilical artery in late pregnancy is significantly related to

18 umbilical cord torsion, which may be a clue for prenatal ultrasound screening of umbilical cord torsion. The

19 Doppler parameters of umbilical artery during umbilical cord torsion are consistent with the basic principle of

20 Doppler parameters change after vascular stenosis in other parts of the human body. It is necessary to conduct

21 multicenter prospective study in the future.

24

1. Introduction 25

26 The umbilical cord is very important for the normal development, survival and health of the fetus after 27 birth. The proper helix of umbilical cord and its tissue structure provide some pressure protection for umbilical 28 vessels^[1-2]. The physiological torsion of umbilical cord can reach 6-11 weeks, and the torsion of umbilical cord can 29 be more than 12 weeks^[3]. Torsion of umbilical cord may lead to fetal growth restriction, premature delivery, meconium contamination of amniotic fluid, and even stillbirth^[4-8]. Umbilical cord torsion as one of the causes of 30 perinatal fetal death^[9]. Prenatal ultrasound has been exploring the ultrasonic manifestation of umbilical cord 31 torsion, but no consensus has been reached^[10,11]. At present, there is no study on the relationship between umbilical 32 cord torsion and the changes of umbilical artery Doppler parameters. The purpose of this study is to explore the 33 34 correlation between umbilical cord torsion and the changes of umbilical artery Doppler parameters, to provide 35 valuable information for prenatal ultrasound screening of umbilical cord torsion, and to explore the possible mechanism of umbilical artery Doppler parameters changes during umbilical cord torsion. 36

2. Materials and Methods 37

38 This study is a retrospective pathological control study.Pregnant women who underwent routine prenatal 39 ultrasound examination and hospital delivery in our hospital from January 2015 to November 2021 were randomly 40 collected.

41 Inclusion criteria:

42 1. Pregnant women who give birth in our hospital have definite discharge diagnosis or pathological diagnosis 43 of placental appendages;

medRxiv preprint doi: https://doi.org/10.1101/2023.11.12.23298437; this version posted November 13, 2023. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in perretuity.

perpetuity. It is made available under a CC-BY-NC-ND 4.0 International license .

44 2.Low-risk pregnancy, including no pregnancy complications or major underlying diseases, such as gestational
 45 hypertension, gestational diabetes, placental previa, placental abruptio, etc.;

3. There is a record of prenatal ultrasound examination in our hospital, and the Doppler parameters of
 umbilical artery are measured in the free segment of umbilical cord during the examination;

- 48 4.Singleton pregnancy.
- 49 Exclusion criteria:
- 50 1.Severe fetal malformations or chromosome abnormalities;
- 51 2.Pregnant women with single umbilical cord artery or other abnormal umbilical cord blood vessels;
- 52 3.Stillbirth or induced labor due to other reasons.

53 Gestational age was calculated based on last menstrual period.If the last menstrual period is unclear, it is 54 calculated and recorded according to the NT cycle after correcting the gestational age.Obstetricians diagnosed the 55 umbilical cord after delivery, and defined those who were discharged as having umbilical cord torsion as the case 56 group, and those who were diagnosed as having no umbilical cord torsion were randomly selected as the control 57 group.The ethics committee of our hospital agreed to waive informed consent for this study.

The ultrasonic instrument uses GE and Mindray color Doppler ultrasound diagnostic machine and the probe frequency is 4~8MHz.The free umbilical cord floating in the amniotic fluid was measured by Doppler, and the measurement Angle was as parallel as possible to the direction of umbilical cord blood flow. Umbilical artery Doppler blood flow parameters, including peak systolic velocity (PSV), umbilical artery blood systolic/diastolic ratio (S/D), resistance index (RI) and pulse index (PI), were extracted from the workstation at each gestational week from 21 to 40 weeks.

64 SPSS26.0 statistical software was used for data processing:1. All umbilical artery Doppler blood flow 65 parameters in the case group and the control group at 21-40 weeks gestation were counted according to gestational 66 age.The mean of each gestational age measurement data in the two groups was calculated; 2. The change trend of 67 umbilical artery blood flow parameters with gestational week was analyzed.3. Logistic regression analysis was 68 performed on the umbilical artery blood flow parameters of the case group and the control group of the same 69 gestational age, P < 0.05, indicating significant differences between the two variables.Regression analysis fills in 70 the missing values.

71

72 **3. Results**

73 This study included 1608 pregnant women who delivered in our hospital (666 in the case group and 942 in the 74 control group). According to the inclusion exclusion criteria, 646 pregnant women (251 in the case group and 395 in 75 the control group) were excluded, and 415 pregnant women in the case group and 547 pregnant women in the 76 control group were finally included. Pregnant women ranged in age from 21 to 44 years, with a mean age of 31 77 years (P > 0.05). A total of 4215 umbilical artery Doppler flow parameters were collected in the case group (1676 78 in the case group and 2543 in the control group), of which basically each included the peak rate of umbilical artery 79 contraction (PSV) and the umbilical artery flow resistance parameters (S/D), and some of them lacked the 80 resistance parameters RI (19) and PI (75) in the umbilical artery group. The average values of umbilical artery 81 Doppler parameters in the case group and the control group at different gestational ages were shown in Table 1, 82 indicating that the average values of PSV, S/D, RI and PI of umbilical artery in the case group were lower than 83 those in the control group at different gestational ages.

The correlation analysis of umbilical artery flow parameters (PSV, S/D, RI, PI) and gestational age in case group and control group respectively showed that the peak velocity of umbilical artery contraction (PSV) was positively correlated with gestational age in both groups, while the correlation parameters of umbilical artery Doppler resistance (S/D, RI, PI) were negatively correlated with gestational age in both groups ($R_{PSV} 0.374$ vs 0.538, $R_{S/D} 0.617$ vs 0.619, $R_{RI} 0.616$ vs 0.563, $R_{PI} 0.602$ vs 0.622, P > 0.05).

After filling in the missing values by regression analysis, Logistic regression analysis showed that:In weeks 22-27, the umbilical artery Doppler parameters of both the case group and the control group were greater than 0.05 in umbilical cord torsion, while in weeks 28-40, the weekly umbilical artery Doppler parameters were less than 0.05, with statistical significance, as shown in Table 2.

96 **4. Discussion**

97 This was a single-center retrospective case-control study. The results showed that the peak velocity of 98 umbilical artery contraction (PSV) was positively correlated with gestational age in both the case group and the 99 control group, and the values of the umbilical artery Doppler resistance related parameters (S/D, RI, PI) were 100 negatively correlated with gestational age.

101 The results of this study showed that there was no significant difference in the mean value of umbilical artery 102 Doppler parameters between the case group and the control group at 21-27 weeks of pregnancy (P > 0.05). The 103 values of umbilical artery Doppler parameters in the 28-40 weeks gestation group were lower than those in the 104 control group, and Logistic regression analysis showed that the difference was significant (P < 0.05). We hypothesize that umbilical cord torsion may begin in early or second trimester, and then gradually increase with 105 106 gestational age.During the second trimester, the protective structure of the umbilical cord gives it some resistance to 107 excessive torsion^[1-2], the changes of umbilical artery blood flow mechanics were not obvious, and the difference of 108 Doppler parameters was not statistically significant. However, with the gradual aggravation of torsion in late 109 pregnancy, the changes of umbilical artery blood flow mechanics were obvious, and the difference of Doppler 110 parameters was statistically significant.

When the arteries in other parts of the human body are narrowed, the Doppler changes of the artery blood flow at the distal end of the stenosis are low-speed and low-pulsation changes, forming a "small slow wave"^[12,13]. We

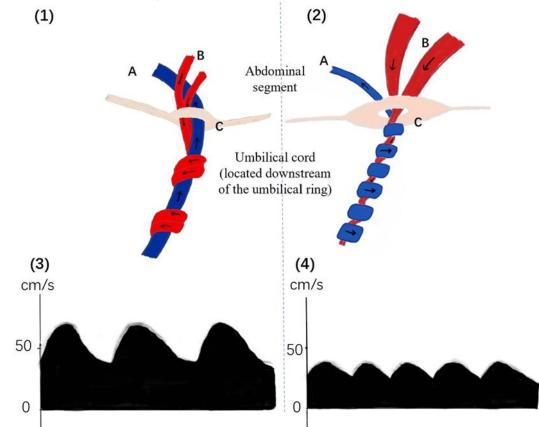

believe that the Doppler changes of umbilical artery blood flow during umbilical cord torsion are consistent with

114 the changes of blood flow Doppler changes after arterial stenosis in other parts: because umbilical cord torsion

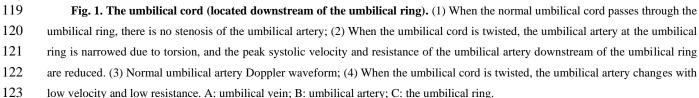

115 occurs mostly at the umbilical wheel^[3], the umbilical artery at the umbilical wheel is narrowed by the torsion of the

116 umbilical cord, resulting in "small slow wave" changes in the blood flow Doppler of the umbilical artery at the

117 distal end of the umbilical wheel (Fig. 1).

perpetuity. It is made available under a CC-BY-NC-ND 4.0 International license .

124 The Doppler parameters of umbilical artery blood flow are the routine indexes of prenatal ultrasound examination. At present, most of the bad pregnancies are related to the abnormal increase of umbilical artery blood 125 Doppler resistance parameters^[14-18]. When obstetricians suspect fetal distress or abnormal fetal movement, they 126 usually pay more attention to the abnormal increase in Doppler resistance of umbilical artery blood flow. If there is 127 128 no abnormal increase in Doppler resistance of umbilical artery blood flow, we often relax our vigilance and think that the fetus is safe for the time being, and it is recommended that the fetus be reexamined in the near 129 future.During the time waiting for reexamination, the fetus may die in the uterus due to torsion of the umbilical 130 131 cord, missing the best rescue opportunity. Therefore, when the fetus has abnormal fetal heart monitoring and 132 abnormal fetal movement, and the Doppler parameters of umbilical artery blood flow do not increase abnormally or 133 decrease instead, the possibility of umbilical cord torsion should be considered. It has been reported that the high 134 helix of umbilical cord is related to umbilical cord torsion^[19-21]. It has been reported that when the umbilical cord is high helical, the umbilical vein blood flow velocity at the umbilical wheel will increase^[22,23] or the a-wave reverse 135 of the venous catheter will occur^[24]. Therefore, when suspected umbilical cord torsion, we also need to pay attention 136 to the contents of unconventional ultrasound examination, such as umbilical cord helix, umbilical vein flow 137 138 velocity and venous catheter spectrum and so on.

Next, we share a case.At 32 weeks of pregnancy, the pregnant woman realized that the fetal movement was
normal, and the fetal heart monitoring in the other hospital showed a poor response. She was referred to our
hospital for further examination. The previous ultrasound examination showed that the double umbilical artery was
found to be a single umbilical artery.

The PSV of umbilical artery was 36.42 cm/s,S/D and 1.84 Magi was 0.46 and Pi was 0.60, in which PSV was 143 lower than normal 5%th^[25], and Spicer D, RI and PI were lower than 10%th^[25](Fig. 2A). Fetal heart rate monitoring 144 145 indicates that the response is poor and the related parameters of Doppler resistance of umbilical artery blood flow are low, suggesting that there may be umbilical cord torsion. Therefore, we examined the shape of the umbilical 146 147 cord and the blood flow of the venous catheter: it was found that the fetal umbilical cord spirally increased, UCI0.76^[26] (Fig. 2B.2C), and the umbilical vein blood flow velocity at the umbilical cord wheel (PSV 69cm/s) was 148 149 higher than that of 95%th^[23](Fig.2D). The a-wave notch of fetal venous duct was significantly deepened and PI increased, which was larger than that of 95%th^[25](Fig.2E).In summary, we considered the possibility of umbilical 150 151 cord torsion, and the obstetrician performed a cesarean section to terminate the pregnancy. The postoperative diagnosis confirmed umbilical cord torsion at 36 weeks (Fig.2F).Postoperative pathology of the placental adnexa 152 153 revealed two umbilical arteries (one of which was atresia) and one umbilical vein.

154

Fig. 2. A case of umbilical cord torsion. A: Abnormal fetal heart monitoring at 32 weeks of gestation, frequency spectrum of umbilical cord free segment. PSV is lower than 5th%, S/D, RI, PI is lower than 10th%. B: 2D image of high spiral umbilical (changing like chain);

159 after birth.

5. Conclusions 160

161 The decrease of umbilical artery Doppler parameters in late pregnancy is significantly correlated with 162 umbilical cord torsion, which may be used as a clue for prenatal ultrasound screening of umbilical cord torsion. The 163 Doppler characteristics of umbilical artery blood flow during umbilical cord torsion are consistent with the basic 164 principle of the changes of blood flow Doppler parameters after vascular stenosis in other parts of the human body. A multicenter prospective cohort study is needed in the future. 165

Abbreviations 166

167 GA: gestational age; PSV:peak systolic velocity; S/D: systolic/diastolic ratio; RI: resistance index; PI: pulsatility 168 index.
