Joint Tensor Factorization algorithm

We adopt the model setting proposed in [1], which can be used to reduce the dimensions jointly between multiple temporal tensors formed by \bar{T}_1 and \bar{T}_2 through the objective function:

$$\min_{\lambda, a_i, 2\xi} \sum_{i,j,t \in T_i} \left((\bar{T}_1)_{ijt} - \lambda_1 a_i b_{ij} \xi_{it} \right)^2 + \sum_{i,j,t \in T_i} \left((\bar{T}_2)_{ijt} - \lambda_2 a_i b_{2j} \xi_{2t} \right)^2$$

Where $q_1 \lambda_1, \lambda_2$ are updated separately.

$$\begin{aligned} \hat{a}_i^{(t+1)} &= \operatorname{argmin}_a \left[\sum_{j,t \in T_i} \left(b_{1j}^{(t)} \xi_{1t}^{(t)} \lambda_1^{(t)} \right)^2 + \left(b_{2j}^{(t)} \xi_{2t}^{(t)} \lambda_2^{(t)} \right)^2 \right] a_i^2 \\ &= \frac{-2 \sum_{j,t \in T_i} \left\{ (\bar{T}_1)_{ijt} \lambda_1^{(t)} b_{1j}^{(t)} \xi_{1t}^{(t)} + (\bar{T}_2)_{ijt} \lambda_2^{(t)} b_{2j}^{(t)} \xi_{2t}^{(t)} \right\} a_i}{\sum_{j,t \in T_i} \left\{ (\bar{T}_1)_{ijt} b_{1j}^{(t)} \xi_{1t}^{(t)} \lambda_1^{(t)} + (\bar{T}_2)_{ijt} b_{2j}^{(t)} \xi_{2t}^{(t)} \lambda_2^{(t)} \right\}} \\ &= \frac{\sum_{j,t \in T_i} \left\{ (\bar{T}_1)_{ijt} b_{1j}^{(t)} \xi_{1t}^{(t)} \lambda_1^{(t)} + (\bar{T}_2)_{ijt} b_{2j}^{(t)} \xi_{2t}^{(t)} \lambda_2^{(t)} \right\}}{\lambda_1^{(t)} \sum_{t \in T_i} \xi_{1t}^{(t)2} + \lambda_2^{(t)2} \sum_{t \in T_i} \xi_{2t}^{(t)2}} \\ \hat{\lambda}_1^{(t+1)} &= \operatorname{arg} \lambda_1 \min \left[\sum_{i,j,t \in T_i} \lambda_1^2 (a_i b_{1j} \xi_{1t})^2 - 2 \sum_{i,j,t \in T_i} (\bar{T}_1)_{ijt} a_i b_{1j} \xi_{1t} \lambda_1 \right] \\ &= \frac{\sum_{i,t \in T_i} (\bar{T}_1)_{itt} a_i b_{it} \xi_{1t}}{\sum_{i,t \in T_i} (a_i \xi_{1t})^2} \\ \hat{\lambda}_2^{(t+1)} &= \frac{\sum_{i,j,t \in T_i} (\bar{T}_2)_{ijt} a_i b_{2j} \xi_{2t}}{\sum_{i,j \in T_i} (a_i \xi_{2t})^2} \\ \hat{b}_{(j)}^{(t+1)} &= \frac{\sum_{i,t \in T_i} a_i \xi_{1t} (\bar{T}_1)_{jit}}{\sum_{i,t \in \pi} (a_i \xi_{1t})^2}, \hat{b}_1^{(t+1)} = \hat{b}_1^{(t+1)} / \left\| \hat{b}^{(t+1)} \right\|_2 \\ \hat{b}_{2j}^{(t+1)} &= \frac{\sum_{i \in I_i} a_i \xi_{2t} (\bar{T}_2)_{ijt}}{\sum_{i,t \in T_i} (a_i \xi_{it})^2}, \hat{b}_2^{(t+1)} = \hat{b}_2^{(t+1)} / \left\| \hat{b}_2^{(t+1)} \right\|_2 \end{aligned}$$

where a are subject loadings, b are feature loadings that can be used to identify features contributing to the beta analysis, $\xi^{(l)}(t)$ is the temporal loading that captures the shared temporal patterns among subjects and features, and λ quantifies the contribution of each component. For each b^1 and b^2 we define W^1 and W^2 respectively given by:

$$\begin{aligned} W^1 &= (\lambda_1 b^{1T})^T \\ W^2 &= (\lambda_2 b^{2T})^T \end{aligned}$$

The temporal covariance and correlations of all features across all input matrices are calculated from the final estimated matrices by:

$$\text{temporal feature covariance matrix} = \begin{bmatrix} \mathbf{W}_1 \\ \mathbf{W}_2 \end{bmatrix} \begin{bmatrix} \mathbf{W}_1 \\ \mathbf{W}_2 \end{bmatrix}^T$$

Which provides the estimated relationships between the features across both input temporal tensors across time.
