LOGISTIC REGRESSION RESULTS

The full model

We analysed the association between PRS and severe COVID-19 using a multivariate logistic regression model adjusted for sex, age, and the first 10 principal components of genetic variation.

Table 1: Logistic regression results for the full model.

	coef	std err	z	P> z 	[0.025	0.975]

- **coef:** the coefficient of the variable (log[odds ratio]);
- **std err:** the standard error of the coefficient;
- **Z:** the z value for the estimated coefficient and the standard error;
- **P>|z|:** the p-value associated with the value in the z value column;
- **[0.025, 0.975]:** 95% confident interval (CI) for the coefficient.

The covariates-only model

The base model contains only the demographic predictors (sex, age, and the first 10 principal components of genetic variation).

Table 2: Logistic regression results for the covariates-only model.

	coef	std err	z	P> z 	[0.025	0.975]

The full model with PRS as a binary predictor

We analysed the association between PRS and severe COVID-19 using a multivariate logistic regression model adjusted for sex, age, and the first 10 principal components of genetic variation. PRS values were considered as a binary predictor, where the highest 10% of PRS were taken as 1, others as 0.

Table 4: Logistic regression results for the full model with PRS as a binary predictor.

	coef	std err	z	P> z 	[0.025	0.975]
intercept	-0.0781	0.223	-0.350	0.726	-0.515	0.359
10% with the highest PRS values	0.9143	0.225	4.069	0.000	0.474	1.355
10% with the lowest PRS values	-1.0727	0.290	-3.703	0.000	-1.640	-0.505
