1 Abstract

Background: Atherosclerosis epitomizes a multifaceted cardiovascular disorder, predominantly characterized by the accumulation of cholesterol-laden plaques within arterial walls. Despite substantial research, the precise mechanisms governing the formation of these cholesterol-rich plaques remain partially elucidated. This study delves into the complex interplay of interleukin-6 (IL-6) receptors, shedding light on their pivotal role in orchestrating cholesterol homeostasis in human macrophages.

Methods: This investigation evaluated the correlation between interleukin-6 (IL-6), its receptors
(IL6R/CD126), and glycoprotein 130 (gp130), alongside established atherosclerosis biomarkers. The
cohort comprised 142 subjects, balanced between lean and obese individuals (71 each). Subsequent
analyses utilized THP-1-derived macrophages to discern the biochemical repercussions of inhibiting IL-6
receptors on cellular mechanisms.

Results: Data indicates a significant upsurge in IL-6 secretion correlating with atherosclerotic 12 13 manifestations in the obese subset, accompanied by a concomitant diminution in IL-6 receptors 14 IL6R/CD126 and gp130 on circulating monocytes within this group. Pharmacological obstruction of the 15 gp130 receptor in macrophages provoked pronounced alterations in lipid metabolism, notably impacting 16 cholesterol management. These alterations were evidenced by an escalated expression of the LDLR gene, 17 responsible for cholesterol uptake, and a surge in de novo cholesterol synthesis, marked by the 18 upregulation of SREBF2 and its downstream effector, mevalonate kinase (MVK). Concurrently, an 19 increase in HMG-CoA reductase protein levels was observed. Intriguingly, a rise in intracellular 20 cholesterol production coupled with a reduction in ABCA1 levels was noted, suggesting a potential 21 impediment in cholesterol efflux in cells deficient in gp130. This hypothesis was further substantiated by Filipin III staining, which indicated cholesterol retention in cells subjected to gp130 inhibition. Clinical 22 23 implications of these discoveries were corroborated through experiments on PBMCs from lean 24 participants, where the gp130 inhibitor curtailed cholesterol efflux to levels comparable to those in 25 untreated cells.

Conclusion: Collectively, our research underscores the instrumental role of gp130 in the reverse cholesterol transport pathway of macrophages. These insights pave the way for novel therapeutic strategies targeting atherosclerosis and its associated cardiovascular complications, spotlighting gp130 as a potential focal point for intervention.

30

31 Introduction

32 Atherosclerosis is a major cause of morbidity and death in developed countries(1). While chronic 33 systemic inflammation is widely acknowledged across all stages of atherosclerosis, it is universally 34 understood that this disorder primarily stems from lipid irregularities, with evidence from the buildup of 35 oxidized low-density lipoproteins (oxLDL) in macrophages within the arterial walls (2). Current insights suggest that during the development of the atherosclerotic lesions, plasma circulatory monocytes migrate 36 37 into the space beneath the endothelium. Here, they evolve into macrophages, ingesting altered 38 lipoproteins, and eventually become foam cells (3). This process is believed to be instigated via cell scavenger receptors like SR-A and CD36 (4) or through the incorporation of cholesterol-bearing 39 lipoprotein particles via the low-density lipoprotein receptor (LDLR) (5), which promotes the 40 41 accumulation of lipids within their cellular structures and leads to the formation of foam cells. Another 42 route to cholesterol-laden macrophages arises from the engulfment of apoptotic cells through 43 efferocytosis (6). All in all, a substantial influx of cholesterol could potentially be harmful if the recycling

44 of cholesterol within macrophages is disrupted (7, 8). It is interesting to point out that atherosclerosis is 45 typically seen alongside other metabolic syndromes such as diabetes mellitus (DM), dyslipidemia and

46 hypertension. Such observation strongly supports the vital impact of systemic inflammatory stimuli. Thus,

- a deeper understanding of the interaction between ox-LDL and inflammatory mediators involved in foam
- 48 cell formation is critical to effectively prevent plaque rupture and the subsequent clinical life-threatening
- 49 complications of atherosclerosis.

50 Interleukin-6 (IL-6) stands out as a notable cytokine within atherosclerotic tissue, with a substantial production originating from macrophages loaded with free cholesterol in advanced lesions (9). IL-6 51 52 receptors, including the primary IL-6 receptor (IL-6R) and the shared signal transducing subunit 53 glycoprotein 130 (gp130), form a crucial duo in orchestrating cellular responses to interleukin-6 (IL-54 6)(10). The IL-6/gp130 complex activates the JAK/STAT3 pathway, triggering a cascade of events that 55 regulate immune and inflammatory responses. It is noteworthy that IL-6 has been established as an 56 independent risk factor for early coronary artery disease (11). Moreover, elevated levels of IL-6 are linked 57 to an increased likelihood of myocardial infarction in healthy men (12). However, the precise role of IL-6 58 remains uncertain especially under different feeding habits, whether it acts as a causative factor, a 59 consequence, or simply a marker of atherosclerosis. Indeed, experiments conducted on genetically 60 modified mouse models predisposed to atherosclerosis reveal contradictory functions of IL-6 (13, 14). For 61 instance, treating mice with recombinant mouse IL-6 resulted in larger lesions in both C57BL/6 and 62 apoE-deficient mice fed a high fat/cholate diet (15). On the other hand, IL6-deficient mice developed 63 larger fatty streak lesions compared to control mice when subjected to an atherogenic diet for 15 weeks 64 (13).

To this end, the interplay between IL-6 receptors and secretion, especially in the cholesterol-rich 65 66 inflammatory environment emblematic of atherosclerosis, is still under exploration. This study aims to discern the expression and correlation of IL-6 receptors (IL-6R/gp130) in human PBMCs isolated from 67 both lean and obese subjects. Our findings indicate that in an obesity context, a spike in IL-6 secretion in 68 69 media corresponds to an augmented cardiovascular risk, evident from the upregulation of total 70 cholesterol. Conversely, the surface expressions of IL-6 receptors (IL6R/CD126) and gp130 were 71 significantly diminished in obese participants. Delving deeper mechanistically using THP-1 transformed 72 macrophages, we observed that the absence of the IL-6 receptor gp130 influenced macrophage cholesterol 73 transport dynamics, amplifying cholesterol influx and curtailing cholesterol efflux, thus influencing 74 macrophage cholesterol equilibrium favoring macrophage foaming.

75

76 Materials and methods:

77 Study Design and Participant Recruitment:

This investigation enlisted 142 individuals from a previously reported cohort (16, 17), all of whom were robust adults devoid of medical conditions, ensuring optimal physical health without any disabilities impeding movement. The study protocol entailed two distinct visits per participant. The initial encounter was dedicated to briefing the participants about the study specifics, potential risks, and subsequent procedures. Post briefing, participants who consented to partake in the study signed an informed consent form and underwent a comprehensive health screening.

- 84
- 85 Data Collection and Assessment Procedures:

86 Subsequent to the initial visit, participants were equipped with wearable accelerometers to monitor 87 physical activity over a span of seven days. The follow-up visit encompassed comprehensive anthropometric and biomedical evaluations. The study adhered to a standardized protocol for all 88 89 anthropometric measurements, employing consistent equipment to ensure uniformity. Height was 90 accurately gauged using a portable stadiometer, with a precision of up to 1.0 cm, while weight 91 measurements were ascertained to the nearest 0.2 kg using a standard physician's beam scale (Detecto). The Body Mass Index (BMI) was computed using the standard formula: weight in kilograms divided by 92 the square of height in meters (kg/m^2) . 93

94

95 Biomedical Evaluations and Ethical Considerations:

96 Post anthropometric assessment, participants proceeded to the phlebotomy unit for blood sample 97 collection. Detailed physical and biochemical profiles of the participants, categorized by BMI, are 98 delineated in Supplementary Table 1. The study was meticulously conducted in strict adherence to the 99 ethical guidelines delineated in the Declaration of Helsinki. Ethical approval for the study was secured 100 from the Kuwait Ministry of Health Ethical Board (Approval ID#: 1806/2021) and the Ethical Review 101 Committee (ERC) of the Dasman Diabetes Institute, Kuwait (Approval ID#: RA MoH-2022-002), 102 ensuring all participants provided written informed consent prior to their inclusion in the study.

103

104 Isolation of human peripheral blood mononuclear cells (PBMC):

Peripheral blood mononuclear cells (PBMCs) were meticulously extracted from EDTA-treated vacutainer
tubes collected from all study participants. The cells were isolated employing the Histo-Paque density
gradient method in conjunction with Sepmate Tubes (StemCell Technologies, Vancouver, CN,
Canada)(18). For the derivation of monocytic cells, the isolated PBMCs were plated in 6-well or 24-well
plates (Costar, Corning Incorporated, Corning, NY, USA) at a density of 3x10⁶ cells per well.

- 110
- 111 Monocytic Cell Cultivation Conditions:

112 The plated cells were cultured in a starvation medium consisting of RPMI-1640 culture medium (Gibco, 113 Life Technologies, Grand Island, NY, USA), enriched with 2 mM glutamine (Gibco), 1 mM sodium 114 pyruvate, 10 mM HEPES, 100 µg/mL Normocin, and 50 U/ml penicillin combined with 50 µg/mL 115 streptomycin (P/S; Gibco). The incubation of the cells was conducted at a controlled temperature of 37°C, 116 in a humidified atmosphere containing 5% CO2. After a period of 3 hours, non-adherent cells were gently 117 removed to ensure the purity of the adherent monocytes. Subsequently, the adherent monocytes were 118 rinsed with serum-free culture medium. The final cultivation phase involved a 24-hour incubation in 119 RPMI supplemented with 2% fetal bovine serum, facilitating optimal cell growth and differentiation 120 under these meticulously controlled conditions.

121

122 *Measurement of blood metabolic markers:*

123 The protocol for assessing blood metabolic markers was rigorously followed as delineated in prior 124 research (19). Prior to the collection of blood samples for plasma isolation, essential physiological 125 parameters, including blood pressure and heart rate, were accurately measured for each participant.

126

127 Plasma Isolation and Biochemical Analysis:

Post-collection, isolated plasma served as the primary medium for the quantitative analysis of various metabolic indicators. This included the measurement of triglyceride levels, total cholesterol, high-density lipoprotein (HDL)-cholesterol, and fasting glucose concentrations. To ensure the reliability and accuracy of the metabolic marker assessments, quality control sera were systematically employed throughout the testing procedures. This meticulous approach underscored the commitment to precision and the integrity

- 133 of the data obtained from these critical biochemical measurements.
- 134

135 Enzyme-Linked Immunosorbent Assay (ELISA) for Biomarker Detection:

For the precise quantification of matrix metalloproteinase 9 (MMP9) and vascular endothelial growth factor (VEGF), the study employed commercially procured enzyme-linked immunosorbent assay (ELISA) kits (R&D Systems, Minneapolis, MN, USA). The assay procedures were meticulously executed in strict accordance with the manufacturer-provided protocols and guidelines established by previously published methodologies. This stringent adherence ensured the reliability and accuracy of the biomarker

- 141 detection, fostering robust and replicable results within the study's framework.
- 142
- 143 Cell Culture and differentiation
- 144 Cultivation and Differentiation of Human Monocytic THP-1 Cells:

145 Human monocytic THP-1 cells, acquired from the American Type Culture Collection (ATCC), were cultured in RPMI-1640 culture medium (Gibco, Life Technologies, Grand Island, USA). The culture 146 147 medium was fortified with 10% fetal bovine serum, 2 mM glutamine, 1 mM sodium pyruvate, 10 mM 148 HEPES, 100 µg/ml Normocin, and 50 U/ml penicillin, along with 50 µg/ml streptomycin (P/S; Gibco, Invitrogen, Grand Island, NY, USA). The cells were maintained under precise conditions at 37°C, in a 149 humidified atmosphere supplemented with 5% CO₂. For experimental purposes, the monocytic cells were 150 151 seeded into 12-well plates (Costar, Corning Incorporated, Corning, NY, USA) at a density of 1×10^6 cells 152 per well, unless specified otherwise.

153

154 *Macrophage Differentiation and Stimulation Protocol:*

Prior to stimulation, the monocytic cells underwent differentiation into macrophages using 10 ng/ml 155 phorbol-12-myristate-13-acetate (PMA) over a period of three days. This was followed by a resting phase 156 of an additional three days in serum-PMA-free RPMI media, ensuring the cells were fully primed for 157 158 subsequent treatments. In the subsequent stimulation studies, differentiated macrophages were initially 159 pre-treated with 10 ng/ml of SC144 (to inhibit the gp130 receptor), recombinant human IL-6 (hrIL-6), or a vehicle control for one hour. Post pre-treatment, the cells were stimulated with Human High Oxidized 160 161 Low-Density Lipoprotein (oxLDL) (KB KALAN Biomedical; Cat no: 770252-4) for a duration of 24 162 hours, setting the stage for the exploration of various cellular responses and interactions under these defined conditions. 163

164

165 *Real-Time Quantitative RT-PCR Process:*

166 The extraction of total RNA was conducted using the RNeasy Mini Kit (Qiagen, Valencia, CA, USA), 167 strictly adhering to the manufacturer's specified protocol. Following extraction, cDNA synthesis was 168 performed utilizing 1 μg of total RNA with the aid of a high-capacity cDNA reverse transcription kit 169 (Applied Biosystems, Foster City, CA, USA). The quantification of gene expression was carried out using 170 the 7500 Fast Real-Time PCR System (Applied Biosystems, Foster City, CA, USA), coupled with the 171 TaqMan® Gene Expression Master Mix (Applied Biosystems, Foster City).

172

173 *Amplification and Data Normalization:*

174 For each reaction, 50 ng of cDNA was amplified using Inventoried TaqMan Gene Expression Assay 175 products. The threshold cycle (Ct) values obtained were normalized against the housekeeping gene GAPDH to ensure accuracy in the relative quantification of the target mRNA. The relative quantities of 176 177 mRNA, in comparison to control samples, were computed employing the $\Delta\Delta$ Ct-method, with the expression levels presented as fold-change relative to the mean expression of the control gene. The 178 179 baseline expression level for the control treatment was set at 1. Data are represented as mean \pm SEM. The 180 threshold for statistical significance was established at p < 0.05. For a comprehensive overview of the 181 primers utilized in the study, refer to Supplementary Table 2, where the primer list is extensively detailed.

- 182
- 183 Western Blotting Procedure:

For Western blot analysis, cells were first collected and then incubated with lysis buffer (comprising Tris 62.5 mM at pH 7.5, 1% Triton X-100, and 10% glycerol) for a duration of 30 minutes. Post-incubation, the cell lysates underwent centrifugation at 14,000x g for 10 minutes, facilitating the separation and subsequent collection of the supernatants. The protein concentration within these lysates was quantitatively assessed using the Quickstart Bradford Dye Reagent, 1x Protein Assay kit (Bio-Rad Laboratories, Inc, CA).

- 190
- 191 Sample Preparation and Gel Electrophoresis:

Protein samples (50 µg in 20 µl) were prepared by mixing with sample loading buffer and then heated for 5 minutes at 95°C. A quantity of 12.5 µg from these prepared samples was loaded and subjected to electrophoretic separation on 12% polyacrylamide gels using SDS-PAGE. Subsequently, the separated cellular proteins were transferred onto Immuno-Blot PVDF membranes (Bio-Rad Laboratories, USA) through electroblotting.

197

198

199 *Membrane Processing and Visualization:*

The membranes were initially blocked using 5% non-fat milk in PBS for one hour to prevent non-specific binding. This was followed by incubation with various primary antibodies (detailed in Supplementary Table 3). After primary antibody incubation, the membranes were washed four times with TBS and then incubated for 2 hours with species-specific HRP-conjugated secondary antibodies (Promega, Madison,

WI, USA). The immunoreactive bands were visualized through the use of the Amersham ECL plus
 Western Blotting Detection System (GE Health Care, Buckinghamshire, UK) and captured using the
 Molecular Imager
 Mercular ChemiDocTM MP Imaging Systems (Bio-Rad Laboratories, Hercules, CA, USA),

 ensuring clear and precise documentation of the protein expression patterns.

208

209 Cholesterol Efflux Assay Implementation:

The measurement of cholesterol efflux was rigorously performed in accordance with the protocol specified by the Cholesterol Efflux Assay Kit (Cell-based) (abcam; ab196985). This involved the incubation of either differentiated cells or isolated PBMCs with labeling and equilibrium mediums. Following this preparatory step, the cells underwent a treatment phase with cholesterol acceptors for a period of four hours, utilizing LDL/VLDL-depleted human serum as the specific cholesterol acceptor for the assay.

216

217 Fluorescence Quantification and Efflux Percentage Calculation:

Post-treatment, the fluorescence emanating from the cell lysate was measured at the wavelengths of 485/523 nm. This fluorescence measurement is critical as it reflects the extent of cholesterol that has been effluxed from the cells. To accurately quantify the percentage of cholesterol efflux, the following formula was applied:

222 % Cholesterol Efflux = (RFU of Supernatant)/ (RFU of Cell Lysate + RFU of Supernatant) x 100

223

224 Flow Cytometry—Staining of Cell-Surface Markers

To determine the expression of IL-6 receptors; IL-6Ra/ CD126 and gp130/CD130 in circulatory monocytes, flow cytometry analysis was conducted using the isolated PBMCs. The cells were first resuspended in FACS staining buffer (BD Biosciences) and subjected to a blocking phase with human IgG (Sigma; 20 μ g) for 30 minutes on ice. Post-blocking, the cells underwent a washing step, followed by resuspension in 100 μ L of FACS buffer.

230 Staining and Incubation Procedures:

For the staining process, the cells were treated with mouse anti-human CD14-PE-Cy[™]7 (cat# 560919, BD Pharmingen[™]), mouse anti-human CD126- APC (cat# 562090, BD Pharmingen[™]), and mouse anti-human CD130- PE (cat# 555757, BD Pharmingen[™]). The stained cells were incubated on ice for a total of 30 minutes, with gentle mixing at 10-minute intervals to ensure uniform staining. This was followed by three washes with FACS buffer and a final fixation step, involving resuspension in 2% paraformaldehyde solution.

- 237
- 238 Intracellular Staining and FACS Analysis:

For intracellular staining, cells were treated with fixation/permeabilization buffer (Cat# 00-5523-00,
eBioscience, San Diego, CA, USA) for 20 minutes at 4°C, then washed and stained with intracellular
inflammatory cytokine rat anti-human IL-6- PE (cat# 554545, BD PharmingenTM). Following staining,

the cells were washed again and resuspended in PBS supplemented with 2% FCS for subsequent FACS
analysis (FACSCanto II; BD Bioscience, San Jose, USA). Data analysis was executed using BD
FACSDiva[™] Software 8 (BD Biosciences, San Jose, USA). To accurately set the thresholds for negative

- versus positive gates, non-stain cells and isotype-specific respective control antibodies were employed.
- 246
- 247 *Oil-Red-O Lipid Staining Procedure:*

248 The visualization of lipid accumulation in treated cells was achieved through the application of Oil-Red-O lipid staining, a technique renowned for its specificity to lipids, primarily triglycerides and lipoproteins.

- 250
- 251 Preparation and Fixation of Cells:

Initially, the treated cells were gently washed with PBS to remove any residual media or non-adherent cells. This was followed by a fixation process, where the cells were immersed in 10% formalin solution

- for a duration of 30 minutes, ensuring the preservation of cellular structures and lipid content.
- 255
- 256 Staining and Visualization Process:

257 Post fixation, the cells were subjected to a series of washes with ddH2O to remove the fixative. 258 Subsequently, the cells were prepared for staining by incubating them in 60% isopropanol for 5 minutes. 259 This step enhances the permeability of the cell membrane, facilitating the effective penetration of the Oil Red O stain. The Oil Red O working solution, freshly prepared and reconstituted with water, was then 260 261 added to the cells and allowed to incubate for 20 minutes. During this period, the lipid components within the cells selectively absorbed the stain. Following the incubation, the excess stain was carefully discarded, 262 263 and the cells were thoroughly washed with ddH2O to remove any non-specifically bound stain. and wre 264 considered ready for visualization under the microscope.

- 265
- 266 Filipin cholesterol staining

Treated cells were fixed using 4% paraformaldehyde, rinsed, and then incubated with Filipin complex (50 μ g/ml) for two hours at room temperature, protected from light. Post-staining, samples were washed and mounted for fluorescence microscopy. Imaging was performed using a UV filter set to specifically capture Filipin's fluorescence with excitation (355 nm) and emission (420 nm) through a standard UV filter block. Image acquisition was standardized to minimize photo-oxidation and fading.

272 BODIPY neutral lipid staining

For the detection of neutral lipids, BODIPY 493/503 was used. After fixing with 4% paraformaldehyde, cells were stained with BODIPY 493/503 at a concentration of 2μ M for 15 minutes at room temperature in the dark. Following staining, cells were washed and mounted for imaging. We used fluorescence microscopy with the appropriate filters to detect BODIPY's green fluorescence at excitation of (493nm) and emission of (503 nm), carefully calibrating the settings to prevent photobleaching.

278 Phalloidin f-actin staining

279 Phalloidin stain (6.6 μ M) diluted with PBS used to incubate the cells for 20min at room temperature, then 280 the cells are visualized under fluorescent microscopy.

- 281
- 282 *Confocal Microscopy Imaging Protocol:*
- 283 Instrumentation and Configuration:

Imaging was conducted using an inverted Zeiss LSM710 spectral confocal microscope (Carl Zeiss, 284 Gottingen, Germany), paired with an EC Plan-Neofluar $40\times/1.30$ oil DIC M27 objective lens. The 285 286 samples underwent excitation utilizing a dual-laser system comprising a 543 nm HeNe laser and the 405 287 nm line of an argon ion laser, ensuring optimal illumination for each specific fluorophore. Following 288 excitation, the emission detection bandwidths were optimized and configured using the Zeiss Zen 2010 289 control software. This careful calibration was crucial for accurately capturing the fluorescence emissions, thereby allowing for precise and detailed visualization of the cellular structures and components under 290 291 study.

292

294

293 Statistical Methodology and Data Presentation:

The statistical analyses were executed using GraphPad Prism software (La Jolla, CA, USA). Data are
 presented as mean ± standard error of the mean (SEM) unless specified otherwise.

- 298 Normality Testing and Group Comparison Methods:
- 299

297

Initial data examination included the Shapiro–Wilk test to confirm normal distribution. For comparative analyses, group means were contrasted using two-tailed tests for parametric data and Wilcoxon–Mann–
 Whitney U tests for non-parametric datasets, ensuring appropriate and robust statistical inference.
 Additionally, for assessments involving three groups, one-way ANOVA and exact Kruskal–Wallis tests were employed for parametric and non-parametric data respectively, catering to the dataset's distribution characteristics.

- 306
- 307
- 308 Correlation Analysis and Significance Thresholds:

Correlation strength and direction between two variables were quantified using Pearson's correlation coefficient "r" for parametric data, and Spearman's correlation coefficient for non-parametric datasets. The significance threshold was set at P < 0.05. The study further delineates levels of significance with notations: ns (non-significant), *P < 0.05, **P<0.01, ***P< 0.001, and ****P < 0.0001, in comparison to control, facilitating a nuanced understanding of the statistical findings in relation to the control group.

- 314
- 315 Results

316 Obese individuals exhibit higher IL-6 plasma levels and reduced expression of IL-6 receptors on

317 *circulatory monocytes.*

To begin investigating the potential role of IL-6 receptors in modulating human macrophages' maintenance of cholesterol homeostasis, we first assessed the secretion of IL-6 cytokine in our cohort.

320 Similar to previous findings, the plasma secretion of IL-6 in our cohort was found to be significantly elevated in obese individuals compared to lean participants (Figure 1A). This observed elevation in IL-6 321 secretion was also observed to be parallel with the increase in atherosclerosis indicators, including total 322 323 cholesterol (Figure 1B), triglycerides (TG) (Figure 1C), and C-reactive protein (CRP) (Figure 1D), while also aligning with the reduction in high-density lipoprotein (HDL) levels (Figure 1E). Further 324 325 correlation analysis showed a significant positive association of IL-6 plasma secretion with adverse atherosclerotic markers including total cholesterol, TG and CRP, whereas as expected a significant 326 327 negative association with HDL (Figure 1F-1I).

328 However, further investigation on the expression and activity of IL6 receptor IL6R/CD126 through flow 329 cytometry defined a different dynamic, as it was observed that lean participants presented a significantly higher representation of $CD14^+CD126^+$ expression on their circulatory monocyte surface (Figure 2A). 330 331 This expression was positively associated with elevated HDL levels in the plasma (Figure 2B) and 332 negatively correlated with lower systolic and diastolic blood pressure in participants (Figure 2F and 2G). 333 However, no significant association was found to other measured atherosclerotic markers including TG, 334 total cholesterol and heart rate (HR) (Figure 2C, 2D, and 2E). We also did not observe any association 335 between IL-6R surface expression and atherosclerotic inflammatory markers CRP, Matrix 336 metallopeptidase 9 (MMP9) or Vascular endothelial growth factor (VEGF) (Figure 2H-2J).

337

Interestingly, when we measured the expression levels of the membrane glycoprotein 130 (gp130) 338 339 transducing chain through flowcytometry analysis of CD130 surface marker, we encountered a higher 340 abundance in all participants with a similar pattern of elevated CD126 expression observed in lean participants compared to those with obesity (Figure 3A). Unlike CD126, the elevated expression levels of 341 gp130 were found to be significantly associated with further favorable lipid markers for atherosclerosis. 342 343 Elevated gp130 expression was positively correlated with higher HDL (Figure 3B) and negatively 344 associated with total cholesterol and TG (Figure 3C and 3D). The elevation of gp130 expression was also found to be associated with significantly reduced systolic and diastolic blood pressure with no impact 345 346 on HR (Figure 3E- 3G). Most importantly, gp130 expression levels was significantly found to be 347 associated with all measured atherosclerotic inflammatory markers (Figure 3H -3J), raising the 348 possibility of a prominent role of gp130 in activating the downstream inflammatory signal for these observed markers. 349

Overall, these results indicate that elevated IL-6 secretion was associated with atherosclerotic indicators in obese individuals, while decrease in IL-6R and gp130 expression on circulatory monocytes was noted in the same cohort. Increased gp130 expression positively correlated with HDL and negatively correlated with total cholesterol, TG in lean individuals indicating a central function of IL-6R and gp130 in controlling pathology of atherosclerosis.

355

356 *Pharmaceutical inhibition of gp130 receptor induces lipid accumulation in macrophages.*

The role of the JAK/STAT3 pathway downstream of gp130 signaling is well documented to promote atherosclerosis development (20). To define the role of this observed decrease in gp130 in atherosclerosis at the molecular level, we treated macrophages derived fromTHP-1 cells with 10ng/ml of the gp130 inhibitor SC144 in the presence and absence of oxLDL. The inhibition of the gp130 receptor had a significant impact on the level of intracellular lipid accumulation within the macrophages; this impact was further enhanced in the presence of oxLDL, showing positive cytoplasmic granularity and neutral lipid

accumulation measured through oil red O staining (Figures 4A and 4B). The influence of SC144 on lipid 363 accumulation was further supported by the increase in PLIN2 gene expression (Figure 4C), which 364 advocates the formation of lipid droplets under gp130 inhibition. Furthermore, we aimed to delve deeper 365 366 into understanding the impact of gp130 inhibition on lipid accumulation by examining the expression of key genes recognized for their control over various facets of lipid metabolism. The inhibition of gp130 367 significantly upregulated low-density lipoprotein receptor (LDLR) gene expression regardless of oxLDL 368 supplementation (Figure 4D). Interestingly, no statistically significant alteration was observed in CD36 369 370 gene expression (Figure 4E), reinforcing the specificity of the observed effects on cholesterol regulation.

Furthermore, our findings present a remarkable reduction in expression of Fatty Acid Binding Protein 4 (FABP4), underscoring the inhibitor's capacity to modulate fatty acid shuttling across the cytoplasm. However, under the influence of oxLDL supplementation, this effect was nullified, giving rise to a pervasive elevation evident in both the vehicle and SC144 test groups (**Figure 4F**). Interestingly, an opposite observation was demonstrated with FABP5 as it showed a significant elevation in its expression under both oxLDL presence and absence (**Figure 4G**).

377 No Significant change in the gene expression of Acetyl-CoA Carboxylase Alpha (ACACA), which serves 378 as the rate-limiting catalyst for long-chain fatty acid biosynthesis (Figure 4H). In contrast, similar to 379 oxLDL treated group, a notable reduction was observed under SC144 treatment in comparison to their 380 respective vehicle control regardless of oxLDL presence. This observation was found in the gene 381 expression of Fatty Acid Synthase (FASN), a downstream component of ACACA (Figure 4I), as well as 382 Diacylglycerol O-Acyltransferase (DGAT), a pivotal enzyme in the metabolic pathway essential for 383 triacylglycerol production (Figure 4J). Furthermore, gp130 inhibition induced significant reduction in β -384 oxidation, since the expression of Acyl-CoA Dehydrogenase Long Chain (ACADL) and both Carnitine 385 palmitoyl transferase 1/2 (CPT1A and CPT2) were reduced compared to controls regardless to oxLDL treatment as well (Figure 4K to 4M). Under gp130 inhibition, the observed profile includes macrophage 386 387 foaming, elevated expression of cholesterol regulatory uptake receptors and fatty acid transportation, and 388 reduced de novo lipogenesis, triglyceride production, and liberation. This suggests an association with 389 increased lipid influx and utilization, reflecting the cell's effort to regulate its response and prevent further 390 uptake and synthesis of fatty acids in the absence of the gp130 receptor. These findings potentially 391 contribute to shifts in lipid metabolism and related pathways, primarily within the realm of cholesterol 392 metabolism.

393

Pharmaceutical inhibition of gp130 receptor modulates cholesterol homeostasis program in
 macrophages.

396 In order to gain deeper insights into the role of the gp130 receptor in macrophage cholesterol 397 homeostasis, we conducted a comprehensive investigation into the impact of the gp130 inhibitor SC144, 398 both in the presence and absence of oxLDL, on a select subset of key genes involved in cholesterol 399 homeostasis. Similar to our previous analysis, we employed quantitative polymerase chain reaction 400 (qPCR) to assess the expression levels of these genes, allowing us to elucidate the molecular mechanisms 401 underlying cholesterol regulation in macrophages. Our initial findings revealed that the inhibition of the 402 gp130 receptor did not elicit a significant alteration in the expression of the Sterol Regulatory Element-403 Binding Transcription Factor 1 (SREBF1) gene when compared to the vehicle control. Interestingly, 404 however, both vehicle-treated and SC144-treated macrophages exhibited a reduction in SREBF1 405 expression upon oxLDL stimulation (Figure 5A). This observation suggests that oxLDL plays a pivotal 406 role in modulating the expression of this gene, irrespective of gp130 inhibition. Remarkably, a

noteworthy trend was observed in the expression of SREBPF2 under conditions of gp130 inhibition,
although this increase did not reach statistical significance. Of particular interest was the finding that
following oxLDL stimulation, the expression of SREBF2 remained significantly elevated in the presence
of gp130 inhibition whereas oxLDL-treated vehicle cells exhibited a significant drop in expression
compared to non-stimulated vehicle cells (Figure 5B). This suggests that gp130 inhibition may contribute
to the sustained upregulation of SREBF2 in response to oxLDL.

The impact of SREBF2 gene expression was further reflected downstream in the expression of 413 Mevalonate Kinase (MVK). Notably, a similar trend of significant upregulation in cholesterol 414 biosynthesis was observed under conditions of gp130 inhibition, regardless of oxLDL stimulation (Figure 415 416 **5C**). These findings indicate a role for gp130 in regulating cholesterol biosynthesis, particularly through 417 the modulation of SREBPF2 and its downstream targets. Additionally, we examined the expression of 418 ATP Binding Cassette Subfamily A Member 1 (ABCA1) and G Member 1 (ABCG1), both of which play 419 crucial roles in cholesterol efflux and are regulated by SREBP2. The inhibition of gp130 resulted in a 420 remarkable suppression of ABCA1 gene expression, which was not rescued even under oxLDL 421 stimulation (Figure 5D). Conversely, no significant difference was detected in ABCG1 gene expression 422 under SC144 treatment compared to the vehicle control, with oxLDL stimulation leading to a reduction in 423 gene expression regardless of gp130 inhibition (Figure 5E). These findings highlight the distinct 424 regulatory roles of gp130 in controlling these efflux-related genes. To further verify this observation, we 425 explored whether gp130 inhibition could affect the total protein levels of cholesterol efflux protein 426 ABCA1 and the cholesterol de novo synthesis enzyme HMG-CoA. Treatment with SC144 significantly inhibited the activation of the gp130 receptor, thereby suppressing the downstream signaling cascade, 427 428 including the phosphorylation of STAT3. Consistent with our mRNA observations, our protein analysis 429 indicated a reduction in ABCA1 protein expression, while HMG-CoA expression was significantly 430 increased, suggesting a potential shift toward cholesterol retention (Figure 5F-5I).

431 We then evaluated the functional significance of these changes through the use of a cholesterol efflux 432 assay, and the results showed that SC144 treatment under oxLDL stimulation significantly increased cellular cholesterol levels by reducing its efflux to the media (Figure 5J). Intriguingly, we further 433 434 examined the subcellular localization of cholesterol by staining with filipin to visualize cholesterol 435 deposits (depicted in blue) and BODIPY 493/503 staining to visualize neutral lipids (depicted in green). Under conditions of gp130 inhibition, we observed an enhanced filipin signal, which partially colocalized 436 437 with areas positive for neutral lipids (Figure 5K). While the semiquantitative nature of this staining 438 necessitates further analyses to elucidate the dynamics of cholesterol and neutral lipids within the plasma 439 membrane after gp130 inhibition, our observations suggest a notable accumulation of intracellular 440 cholesterol in the treated group. In an attempted to translate this observation to a human ex-vivo model, 441 we assessed the cholesterol efflux capacity of peripheral blood mononuclear cells (PBMCs) isolated from 442 both lean and obese individuals. Furthermore, PBMCs obtained from lean subjects were pre-treated with SC-144, simulating the gp130 inhibitory milieu observed in obese participants. Fascinatingly, PBMCs 443 444 from lean individuals exhibited superior cholesterol efflux capabilities compared to those from obese 445 counterparts. Notably, upon gp130 inhibition, the cholesterol efflux potential of these cells was markedly 446 attenuated, aligning closely with patterns observed in obese-derived PBMCs (Figure 5L). Collectively, 447 our findings pertaining to gene and protein expression profiles underscore the involvement of cholesterol 448 metabolism, particularly through pathways related to cholesterol synthesis and uptake, as influenced by 449 gp130 inhibition. However, this increase in cholesterol synthesis is not matched by an equivalent increase 450 in cholesterol clearance, as evidenced by the reduction in ABCA1 expression. These results shed light on 451 the intricate interplay between gp130 signaling and macrophage cholesterol homeostasis.

455 Discussion

456 Obesity is characterized as a chronic inflammatory condition, and it is considered a major risk factor for 457 the development of atherosclerosis. Under obesity setting, the elevation of several macrophage-induced 458 chemokines and cytokines has been promoted as a key mediator of local and systemic inflammation, 459 oxidative stress, and abnormal lipid metabolism within the arterial walls. Under these contacts, the role of 460 IL-6 cytokine specifically in the development of atherosclerosis has long been debated, as its elevation in atherosclerotic patient plasma has been reported by several groups. Regardless, the direct impact of 461 462 circulatory IL-6 on the progression of atherosclerosis remains not well defined. In this work, we aimed to characterize IL-6 cytokine secretion and IL-6R/gp130 receptor signaling in both lean and obese 463 464 population and correlated our findings with atherosclerosis risk markers. Our findings provide compelling 465 insights into the molecular intricacies of atherosclerosis, particularly the role of IL-6 receptors in 466 modulating human macrophage cholesterol homeostasis. The marked decrease in IL-6 receptors expression on circulatory monocytes in obese individuals, specifically gp130 despite elevated IL-6 467 secretion, suggests a complex regulatory mechanism that requires intensive further investigation. Similar 468 to IL-6 secretion, the role of gp130 under inflammatory setting seemed to be diverse. In a study 469 470 conducted by Duan et al, (21) it was demonstrated that CD146 interaction with gp130 and the subsequent 471 activation of its signal is a major promoter of adipocyte infiltrated macrophages and a driven trigger for 472 these macrophages to polarize toward a pro-inflammatory phenotype. However, this activation of pro-473 inflammatory response downstream of gp130 is also debated upon its protective outcome in part, by 474 increasing the expression of suppressor of cytokine signalling-3 (SOCS3) (22, 23). Regardless, the role of gp130 expression seems to play a different role in metabolic diseases such as diabetes, obesity, and 475 476 atherosclerosis. In a work presented by *Carbonaro et al*, it was shown that by restoring hepatic IL-6-477 gp130 signaling pathway through constitutive activation of gp130 substantially reduced lipid 478 accumulation in human hepatocytes thus, preventing hepato-steatosis (24). This influence of gp130 479 activation was further demonstrated to be a vital signal mediator in exercise induced weight reduction (25, 480 26).

481 Indeed, in our mechanistical investigation, we observed an increase in intracellular lipid accumulation 482 when macrophages were treated with gp130 inhibitor, as evidenced by increased cytoplasmic granularity and neutral lipid content, suggesting a direct impact of gp130 inhibition on lipid uptake and storage 483 mechanisms. This is further corroborated by the upregulation of the PLIN2 gene, a marker of lipid droplet 484 formation. To further identify the intricate of this lipid induction, we conducted a broad gene analysis of 485 for different lipid processing genes. Even though all lipid uptake and shuttle genes showed significant 486 487 upregulation under the stimulation of oxLDL, an interesting notable increase in LDLR expression under 488 gp130 inhibition regardless of oxLDL supplementation hinted at a possible enhanced cholesterol uptake 489 capacity. Moreover, similar observation was found in the expression of FABP5. Several studies have implicated both FABP4 and FABP5 in atherosclerotic lesions formation (27-29). However, it is very 490 491 interesting to note that while FABP4 was only marginally detected in early and advanced lesions, the 492 presence of FABP5 is found to be expressed abundantly in these lesions. This increase in expression of 493 FABP5 is also found in areas mostly restricted to infiltrated foam cells (30). Furthermore, the association 494 between FABP5 in particular and macrophage cholesterol efflux capacity (31) further supported the 495 impact of gp130 inhibition on cholesterol regulation.

496 The absence of significant changes in ACACA expression, coupled with the observed reductions in

FASN and DGAT gene expression, indicates a dampened *de novo* lipogenesis and triglyceride production
under gp130 inhibition. This is consistent with a cellular attempt to limit further fatty acid synthesis in

499 response to heightened lipid influx.

Another interesting observation we had was the influence of gp130 inhibition on downregulating genes 500 501 involved in β -oxidation, such as ACADL and CPT1A/CPT2. In a recent work presented by Zheng et al, it 502 was demonstrated that the influence of Atorvastatin; a statin medication used for the control of cholesterol levels, induced cardiac pleiotropic effects through inactivating p-STAT3, a transcription factor 503 504 downstream of gp130 causing the inhibition of CPT1 signaling and thus inhibiting fatty acid oxidation 505 (FAO) (32). Even though the authors believe that this effect holds a protective impact in preventing cardiac hypertrophy and dysfunction, it also further supports a state of altered lipid utilization and 506 507 metabolism that is specifically tailored towards cholesterol homeostasis.

508 Paying more attention to the influence of gp130 on cholesterol homeostasis in the presence and absence 509 of oxLDL supplementation, we conducted further characterization analysis of key genes involved in 510 cholesterol de novo biosynthesis, storage, and exportation. The activation of the membrane-bound transcription factors SREBPs in both cholesterol synthesis as well as fatty acid synthesis has been well 511 512 characterized, beside them being a driven factor for both cholesterol and fatty acid production, they also 513 provide the mean by which cellular cholesterol exerts negative feedback on cholesterol synthesis (33, 514 34). It is not surprising to observe a reduction in SREBF1 and SREBF2 gene expression under the 515 stimulation of oxLDL when compared to vehicle control. However, the use of SC144 to inhibit gp130 516 activity induced a sustained elevation in SREBF2 that was found not to be reduced under oxLDL 517 stimulation. We believe that this sustains upregulation in SREBF2 subsequently aided the upregulation 518 seen MVK gene expression consequently producing more HMG CoA reductase protein. Nonetheless, as we noticed this upregulation of cholesterol biosynthesis induced by the inhibition of gp130, we also 519 520 observed strong inhibitory effect seen on ABCA1 at both its gene and protein levels. This observation 521 suggests that under gp130 inhibition this observed intracellular lipid accumulation is more likely to be 522 caused by cholesterol retention. Indeed, cholesterol immunofluorescence staining with Filipin III further defines this impact of cholesterol retention within gp130 inhibited cells. However, this impact was further 523 524 defined when we investigated the mechanistic ability for THP-1 transformed macrophages to efflux 525 cholesterol under oxLDL stimulation, we found that their ability was significantly abolished when treated with SC144 inhibitor. Translating these findings into a primary human model, we observed that the ability 526 527 of lean individuals to probably efflux cholesterol from there macrophages indeed seems to be dependent 528 on gp130 activation, as when we pre-treated lean individuals PBMCs with SC144 we observed significant reduction in these cells' ability to efflux cholesterol to a point where they became similar to 529 530 obese individuals isolated cells and most likely due to similar impact identified in our THP-1 model.

531 In conclusion, the findings of this study shed light on the intricate dynamics of IL-6 receptors and their

potential role in modulating human macrophage cholesterol homeostasis. By unraveling these molecular

533 intricacies, this research lays the groundwork for future therapeutic interventions aimed at mitigating the

progression of atherosclerosis and related cardiovascular diseases.

Figure 1. IL-6 secretion is elevated in obese individuals' plasma and is associated with markers linked to atherosclerosis.
IL-6 was determined in the plasma samples of lean and obese individuals using ELISA(A). Markers linked to atherosclerosis
were determined. (B) Total cholesterol, (C) TG, (D) CRP, and (E) HDL. Two-tailed /Wilcoxon–Mann–Whitney U tests were

- vsed to assess the differences between Lean vs Obese. Pearson's/Spearman's correlation coefficient and linear regression analysis
- 719 was conducted to investigate the relationship between secreted IL-6 cytokine and atherosclerosis related markers (F-I). All data
- are expressed as mean \pm SD. P \leq 0.05 was considered statistically significant (**P < 0.01, ****P < 0.0001).

739Figure 3: IL-6 trans-membrane receptor gp130 is markedly decreased in obese individuals' circulatory740monocytes. PBMCs were isolated from human blood samples obtained from lean and obese individuals. (A) Bar-graph of Flow741cytometry analysis of CD14⁺CD130⁺ subset percentages, (B) Representative dot-plot analysis of CD14⁺CD130⁺ subset742expression (B-J) Correlation between CD14⁺CD130⁺ subset percentages and atherosclerosis related markers. Data are presented743as mean \pm SD. *p \leq 0.05, **p \leq 0.001, ****p \leq 0.0001.

Figure 4: Pharmaceutical inhibition of gp130 receptor induces lipid accumulation in macrophages derived from
 THP-1 cells. Macrophages were pre-treated with gp130 inhibitor or vehicle control followed by stimulation with OxLDL (150uM; Thermo # L34357). (A) Representative dot plot of cellular granulation of macrophages with representative image of Oil red O staining. (B) Smi - quantitative analysis of Oil red O extraction. (C) Gene expression analysis of PLIN2. (D) Gene expression of LDLR. (E) Gene expression of CD36. (F) Gene expression of FABP4. (G) Gene expression of FABP5. (H) Gene expression of ACACA. (I) Gene expression of FASN. (J) Gene Expression of DGAT. (K) Gene Expression of ACADL. (L) Gene expression of CPT1A and (M) Gene expression of CPT2. Data are presented as mean ± SEM values (n=3-4) and compared

756 between groups using one-way ANOVA with Tukey's multiple comparisons test. *p≤0.05, **p≤0.01, ***p≤0.001, ****p≤0.0001.

758 Figure 5

759 Figure 5: Pharmaceutical inhibition of gp130 receptor modulates cholesterol homeostasis in macrophage 760 transformed THP-1 cells. THP-1-derived macrophages were pre-treated with gp130 inhibitor or vehicle control followed by 761 stimulation with OxLDL (150uM; Thermo # L34357). QRT-PCR analysis was conducted for (A) SREBP1 gene expression. (B) 762 SREBP2 gene expression. (C) MVK gene expression. (D) ABCA1 gene expression. (E) ABCG1 gene expression. Western Blot 763 analysis for protein expression for (F) phospho-STAT3 corrected over β-actin. (G) ABCA1 corrected over β-actin. (H) HMG-

- 764 COA corrected over β-actin. (I) Representative immune blots for protein expression. (J) Cholesterol efflux assay conducted for
- 765 THP-1 transformed macrophages treated with SC144. (K) Immun-floresence microscopy images of treated THP-1 transformed
- 766 macrophages stained with filipin III cholesterol stain (Blue), BODIPY 493/503 for neutral lipids (Green) and Phalloidin to
- $\label{eq:actin} 1200 \mbox{ labeled actin filaments (red) (Scale Bar 5 \mu M). (L) Cholesterol efflux assay conducted on isolated and treated PBMC from both$
- Tean and Obese individuals. Data are presented as mean ± SEM values (n=3-4) and compared between groups using one-way
- ANOVA with Tukey's multiple comparisons test. $p \le 0.05$, $p \le 0.01$, $p \le 0.001$, $p \le 0.001$.
