Supplementary methods

Quality assessment criteria.

Criteria

1. Study participation; Study sample adequately represents the population of interest

- (A) Description of the key characteristics of the study population (distribution by age, gender and ancestry/ethnicity)
- (B) The sampling frame and recruitment are described, including characteristics of the place of recruitment or authors clearly reference where this information can be found
- (C) Inclusion and exclusion criteria are described or authors clearly reference where this information can be found
- (D) Information about participation at baseline and potential attrition (for genetic data) are described or authors clearly reference where this information can be found

2. Predictor measurement; autism polygenic score is adequately measured

- (E) Description of genetic data collection (e.g., blood, saliva) and genotyping (array) is provided, and target sample was not part of GWAS
- (F) Genetic data were subject to adequate quality control (minor allele frequency, missing rate, relatedness participants, sex mismatch, and genotype quality), an up to date imputation method and an established reference panel was used
- (G) The autism polygenic score is adequately calculated (e.g., pruning/clumping of SNPs), and the p-value threshold for calculating the autism polygenic score is reported.

3. Outcome measurement; Outcome of interest is measured in a similar way for all participants

- (H) A clear definition of the outcome measures is provided
- (I) Several indications are provided for the validity and reliability of the outcome measure, or a reference is provided.
- (J) The method and setting of outcome measurement is the same for all study participants

4. Confounding measurement; Important potential confounders are appropriately accounted for

- (K) Age, gender and Socio Economic Status are accounted for in the analysis
- (L) Population stratification and potential batch effects are accounted for in the analysis
- (M) In case of clinical samples, treatment and comorbidity are accounted for in the analyses

5. *Analysis and data presentation; Statistical analysis is appropriate*

- (N) Sufficient presentation of the data to assess the adequacy of the analytic strategy
 - (O) The number of participants in the target sample supports sufficient statistical power (N > 400)
 - (P) The selected statistical model is adequate for the design of the study
 - (Q) There is no evidence of selective reporting of results, and proper correction for multiple testing was applied.
-

Supplementary results

Abbreviations:

ANT: Attention Network Test

BISBAS: Behavioral Inhibition and Behavioral Activation

BRIEF: Behavior Rating Inventory of Executive Function

CBCL: Child Behaviour Checklist

DAWBA: Development and Wellbeing Assessment

GBI: General Behavior Inventory

GSCE: General Certificate of Secondary Education

KSADS: Kiddie Schedule for Affective Disorders and Schizophrenia

NIH: National Institute of Health

OCD: Obsessive Compulsive Disorder

PARCA: Parent Report of Children's Abilities

SCDC: Social and Communication Disorders Checklist

SDQ: Strengths and Difficulties Questionnaire

UPPS-P: Impulsive Behavior Scale

WASI: Wechsler Abbreviated Scale of Intelligence

WISC: Wechsler Intelligence Scale for Children

WRAT: Wide Range Achievement Test

Primary results

General psychopathology

Systematic review. Seven studies assessed the association between the autism polygenic score and general psychopathology¹⁻⁷. This category included studies that used general mental health questionnaires to assess general psychopathology, either by using the p-factor (the p factor reflects a general propensity towards psychiatric diagnoses) or by analysing total scores and subscale scores from these questionnaires.

Overall liability for mental health issues. Two studies reported a non-significant association with the Child Behaviour Checklist (CBCL⁸) total scale or the KSADS total scale^{1,2}, and one reported a significant association⁷. Two studies did not report an association with p-factor constructed from the CBCL³ or a p-factor constructed from the DAWBA and SCDC⁴.

Questionnaire (sub)scales. Included studies used the CBCL⁸, the GBI⁹, a three-item prosocial behaviour survey, the UPPS-P¹⁰, the BISBAS¹¹, KSADS¹² and the SDQ¹³.

For the CBCL, patterns of significant associations appear to be random: Gui et al. (2022)¹ and Thomas et al. (2022)⁶ do not report significant associations with any CBCL subscales. Loughnan et al. (2022) only report an association with the caregiver reported inattention subscale of the CBCL, whereas Waszczuk et al. (2021)⁷ find several associations with factors composed from the CBCL; externalizing, neurodevelopmental and detachment.

For the KSADS, Loughnan et al. (2022)² report an association with the self-reported depression symptoms in a mixed-ancestry sample and caregiver reported OCD symptoms in a non-European sample, self-reported depression, and suicidality symptoms, and caregiver reported ADHD. No association with other subscales was reported.

For the SDQ, In the ALSPAC sample, Schlag et al. (2022)⁵ reported only one association with parent reported low prosociality in 7 year-olds, but not with any other parent or teacher reported low prosociality or peer problems. In the TEDS sample however, they do find several significant associations (low prosociality at age 7 and 11, peer problems at age 7, 9, 12 and PR peer problems at age 4, 7, 11).

Meta-analysis. Standardized beta coefficients ranged from -.143 to .292. The overall meta-analysed correlation coefficient was $r = .035$ (95% CI .03 - .04). Total I^2 was 91.5%, of which 1.0% between-study and 90.5% within-study. Meta-analysis results for general psychopathology, are presented in Supplementary Figure 8.

Cognition and executive function

Systematic review. Nine studies assessed the association between the autism polygenic score and cognition and executive function^{1,2,14–20}. Included studies used the NIH toolbox cognition battery²¹, WISC, WASI, WRAT3, WRAT4, BRIEF, educational attainment (GSCE), PARCA, Stroop test, Trail-making test, digit span test, n back test, and ANT. Only 4 out of 40 measures were significant (10%). Three were a positive association with crystallized memory in samples of different ancestries². However, another study did not support this association in an overlapping sample¹. The other association was a negative association with behaviour regulation measured using BRIEF¹⁹

Meta-analysis. Standardized correlation coefficients ranged from -.338 to .170. The overall meta-analyzed correlation coefficient was $r = .042$ (95% CI -.008 - .075). Total I^2 was 94.1%, of which 88.4% between-study and 5.7% within-study. Meta-analysis results for cognition and executive function, are presented in Supplementary Figure 9.

Physical wellbeing

Systematic review. Eight studies assessed the association between the autism polygenic score and physical wellbeing^{22–29}. Physical wellbeing included phenotypes such as activity levels, general health and health before and during pregnancy, nutrient intake, smoking and alcohol consumption, sleep problems, BMI and immune marker levels. Only 5 out of 181 (2,8%) outcome measures were significantly associated with the autism polygenic score. This included a negative association with overall activity levels²² and the level of immune marker sIL-2R²⁸.

Meta-analysis. Standardized correlation coefficients ranged from -.198 to .166. The overall meta-analyzed effect size was $r = .016$ (95% CI .006 - .026). Total I^2 was 98.3%, of which 1.5% between-study and 96.8% within-study. Meta-analysis results for physical wellbeing, are presented in Supplementary Figure 10.

Early neurodevelopment

Systematic review. The category of early neurodevelopment included nine studies on eye tracking measures ($n = 3$) and other neurodevelopmental traits such as motor development and temperament^{20,30–37}. Nine out of 43 tested associations were reported as significant; motor difficulties at age 3³⁰, age at first walking³³, overall neuromotor development and overall muscle tone and low and high muscle tone³⁶, gross motor skills and receptive language development³⁷.

Meta-analysis. Standardized correlation coefficients ranged from -.110 to .112. The overall meta-analyzed correlation coefficient was $r = .013$ (95% CI -.038 – .066). Total I^2 was 94.2%, of which 93.3% between-study and 0.9% within-study. Meta-analysis results for early neurodevelopment are presented in Supplementary Figure 11.

Emotion recognition

Systematic review. Three studies assessed the association between the autism polygenic score and emotion recognition. Reed et al. (2020)³⁸ do not report a significant association with emotion recognition in healthy participants. Qin et al. (2020)³⁹, on the other hand, do report a negative association of autism polygenic score with recognition of negative emotions and total emotion recognition, but not positive or neutral emotions. Waddington et al. (2021)⁴⁰ studied how autism polygenic score relates to speed and accuracy of visual and auditory emotion recognition, and only find that it associates with faster visual emotion recognition.

Meta-analysis. Standardized beta coefficients ranged from $-.229$ to $.400$. The overall meta-analyzed correlation coefficient was $r = .18$ (95% CI $-.034 - .381$). Total I^2 was 99.0%, of which 36.6% between-study and 62.3% within-study. Meta-analysis results for emotion recognition are presented in Supplementary Figure 12.

Brain measures

Systematic review: Nine studies assessed the association between the autism polygenic score and brain measures. This category included MRI and EEG measures. The autism polygenic score was significantly positively associated with an accumulated measure of neuroanatomical atypicality for cortical thickness⁴¹, shorter N290 latency to face vs nonface stimuli⁴², increased salience network connectivity with the postcentral gyrus in autistic and typically developing youth (significant sex differences were observed⁴³), functional annotations related to language, executive functions and autism⁴⁴, longer N170 latency to face response⁴⁵, and higher amplitude of low frequency fluctuation in the left amygdala in schizophrenia cases and controls³⁹. The autism polygenic score was not associated with cortical measures of autism-related brain regions, including surface area, thickness, and subcortical volume and gyrification measurements^{44,46}, nor with resting-state fMRI or diffusion tensor imaging (DTI) measurements¹, and neither with global and tract-specific fractional anisotropy and mean diffusivity⁴⁷.

Meta-analysis: One study was excluded from the meta-analysis since effect sizes were not reported (Gui et al., 2022). Standardized regression coefficients ranged from $-.364$ to $.57$. The overall meta-analyzed effect size was $r = .160$ (95% CI $.031 - .288$). Total I^2 was 99.9% of which 80.5% between-study and 19.4% within-study. Meta-analysis results for brain measures are presented in Supplementary Figure 13.

Phe-WAS

Systematic review. Three studies applied a phenome-wide association approach^{44,48,49}, where a large number of outcomes is tested for its association with the autism polygenic score in a similar way genetic variants are tested for an association with an outcome in GWAS. From the 3238 tested variables by Sha et al. (2021)⁴⁴, four showed a significant association with autism polygenic score (hearing difficulty/problem with background noise, Townsend deprivation index at recruitment, Qualifications: College or University degree and Long-standing illness, disability or infirmity). In the same sample of residents of the UK but using a much larger number of outcomes (23004), Leppert et al. (2020)⁴⁸ find 10 significant

associations, most of which were related to physical health (blood measures, body size, lung function), and some related to mental health (nervousness) and socio-demography. Wendt et al. (2020)⁴⁹ applied phe-was in a US based sample and specifically focused on 491 neurodevelopmental outcomes, and found a significant association with recognition of angry faces and nominal associations with other emotion recognition phenotypes.

Meta-analysis. No meta-analysis was performed considering the outcome variables in this category were too extensive.

Other

Systematic review. In the 21 studies with uncategorized outcome measures, autism polygenic score was negatively associated with having potentially damaging (rare) genetic variants⁵⁰, age at onset of bipolar disorder⁵¹ and age at onset of schizophrenia (in a Japanese sample⁵²), and was positively associated with female sex⁴⁴, non-righthandedness⁴⁴, paternal age²³, comorbid conditions related to allergies⁵³, higher population density in adult life and moving from rural areas to cities⁵⁴, increased Deoxyribonucleic acid (DNA) methylation⁵⁵, childhood trauma^{56,57}, experiencing physical/emotional abuse and physical assault⁵⁸. No associations were reported with age⁵⁹, age at first parental concern and age of autism diagnosis²⁰, polarity at onset of bipolar disorder⁵¹, sleep disturbance in children²⁷, gestational age¹⁶, vocabulary⁵⁹, reading⁵⁹, parental educational level¹⁹, several outcomes related to eating disorders (e.g. age of diagnosis, lowest BMI during adulthood, ever been in inpatient or outpatient care; Zhang et al., 2022), use of depression or anxiety medication²³, maternal age²³, response to social skills group training⁶⁰, trajectories of social wariness and preference for solitude⁶¹, adulthood trauma⁵⁶, sexual abuse⁵⁸.

Some studies reported inconsistent associations. Autism polygenic score was negatively associated with the odds of childhood infections in people in the third quartile of the polygenic score, but there was no association in the first, second and fourth quartile⁶². The autism polygenic score was positively associated with hoarding symptoms in some, but not all samples included in Strom et al. (2022)⁶³, and the meta-analyzed result was only significant when heterogeneity between samples was not accounted for.

Meta-analysis. No meta-analysis was performed considering the outcome variables in this category were too diverse.

Secondary results

Systematic review: Sex differences

Sex differences were assessed in 14 of the 72 included studies. Overall, there is little evidence for sex differences in associations of autism polygenic score with outcomes^{14,35,36,44,54,54,64}. Yet some differences were reported; the autism polygenic score had a stronger association in boys for repetitive behavior, social communication³⁰ and age at first walking³³. The autism polygenic score had a stronger association in women for childhood trauma⁵⁷, sameness⁶, and psychiatric behavior¹. Some studies assessed the influences of autism polygenic score in mothers and fathers^{23,65}, but they reported no differences in the associations.

Meta-analysis: Population differences in polygenic score association with autism diagnosis

Based on recent work that pointed out how polygenic score accuracy may vary not only between genetic ancestries, but within ancestries too⁶⁶, we performed secondary analyses assessing whether the polygenic score association differed between Europe and US-based samples. For EU-based samples, the association between autism polygenic score and autism diagnosis was $r = .20$ (95% CI .12 – .28) whereas the association for US-based samples was $r = .12$ (95% .02 – .21). A test for subgroup differences revealed no significant difference between these populations, $Q = 2.77$ $df = 2$, $p = .25$. Meta-analysis results for autism diagnosis, including subgroup analyses, are presented in Figure 2.

Meta-analysis: Analyses for Subclassifications within Specific Psychiatric Classifications

Our secondary results show that the autism polygenic score only significantly associates with the subclassification ‘psychotic spectrum’, but not ADHD, eating disorders, or self-harm and suicide ideation, see sFigure 7.

Section and Topic	Item #	Checklist item	Location where item is reported
TITLE			
Title	1	Identify the report as a systematic review.	Title page
ABSTRACT			
Abstract	2	See the PRISMA 2020 for Abstracts checklist.	Main manuscript, P1
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of existing knowledge.	Main manuscript, P2-P3
Objectives	4	Provide an explicit statement of the objective(s) or question(s) the review addresses.	Main manuscript, P3
METHODS			
Eligibility criteria	5	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	Main manuscript, P4
Information sources	6	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	Main manuscript, P4
Search	7	Present the full search strategies for all databases, registers and websites, including any filters and limits used.	Supplemental

Section and Topic	Item #	Checklist item	Location where item is reported
strategy			material, sTable 2
Selection process	8	Specify the methods used to decide whether a study met the inclusion criteria of the review, including how many reviewers screened each record and each report retrieved, whether they worked independently, and if applicable, details of automation tools used in the process.	Main manuscript, P4
Data collection process	9	Specify the methods used to collect data from reports, including how many reviewers collected data from each report, whether they worked independently, any processes for obtaining or confirming data from study investigators, and if applicable, details of automation tools used in the process.	Main manuscript, P4
Data items	10a	List and define all outcomes for which data were sought. Specify whether all results that were compatible with each outcome domain in each study were sought (e.g. for all measures, time points, analyses), and if not, the methods used to decide which results to collect.	Main manuscript, P4
	10b	List and define all other variables for which data were sought (e.g. participant and intervention characteristics, funding sources). Describe any assumptions made about any missing or unclear information.	Main manuscript, P4
Study risk of bias assessment	11	Specify the methods used to assess risk of bias in the included studies, including details of the tool(s) used, how many reviewers assessed each study and whether they worked independently, and if applicable, details of automation tools used in the process.	Main manuscript, P5
Effect measures	12	Specify for each outcome the effect measure(s) (e.g. risk ratio, mean difference) used in the synthesis or presentation of results.	Main manuscript, Table 1
Synthesis methods	13a	Describe the processes used to decide which studies were eligible for each synthesis (e.g. tabulating the study intervention characteristics and comparing against the planned groups for each synthesis (item #5)).	Main manuscript, P4
	13b	Describe any methods required to prepare the data for presentation or synthesis, such as handling of missing summary statistics, or data conversions.	Main manuscript, P6

Section and Topic	Item #	Checklist item	Location where item is reported
	13c	Describe any methods used to tabulate or visually display results of individual studies and syntheses.	Main manuscript, P6
	13d	Describe any methods used to synthesize results and provide a rationale for the choice(s). If meta-analysis was performed, describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used.	Main manuscript, P6
	13e	Describe any methods used to explore possible causes of heterogeneity among study results (e.g. subgroup analysis, meta-regression).	Main manuscript, P6
	13f	Describe any sensitivity analyses conducted to assess robustness of the synthesized results.	Main manuscript, P7
Reporting bias assessment	14	Describe any methods used to assess risk of bias due to missing results in a synthesis (arising from reporting biases).	Main manuscript, P6
Certainty assessment	15	Describe any methods used to assess certainty (or confidence) in the body of evidence for an outcome.	-
RESULTS			
Study selection	16a	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	Main manuscript, Figure 1
	16b	Cite studies that might appear to meet the inclusion criteria, but which were excluded, and explain why they were excluded.	Main manuscript, P5
Study characteristics	17	Cite each included study and present its characteristics.	Main manuscript,

Section and Topic	Item #	Checklist item	Location where item is reported
			Table 1
Risk of bias in studies	18	Present assessments of risk of bias for each included study.	Supplemental Material, sTable 3
Results of individual studies	19	For all outcomes, present, for each study: (a) summary statistics for each group (where appropriate) and (b) an effect estimate and its precision (e.g. confidence/credible interval), ideally using structured tables or plots.	Main manuscript, Table 1
Results of syntheses	20a	For each synthesis, briefly summarise the characteristics and risk of bias among contributing studies.	Main manuscript, Table 2 and Supplemental Material, sTable 3
	20b	Present results of all statistical syntheses conducted. If meta-analysis was done, present for each the summary estimate and its precision (e.g. confidence/credible interval) and measures of statistical heterogeneity. If comparing groups, describe the direction of the effect.	Main manuscript, P136-141 and Supplemental Material, Results

---------------------	-----	---	---	---	-----	---	---	---	---	-----	-----	---	-----	---	---	---	---	---

Note. Studies highlighted in gray have been presented earlier in the table due to them being in multiple outcome categories. A bias is detected when > 50% of the criteria within one domain are scored -. Criterium M was not taken included when counting biases.

sTable 4. Rosenthal's fail-safe N per outcome category

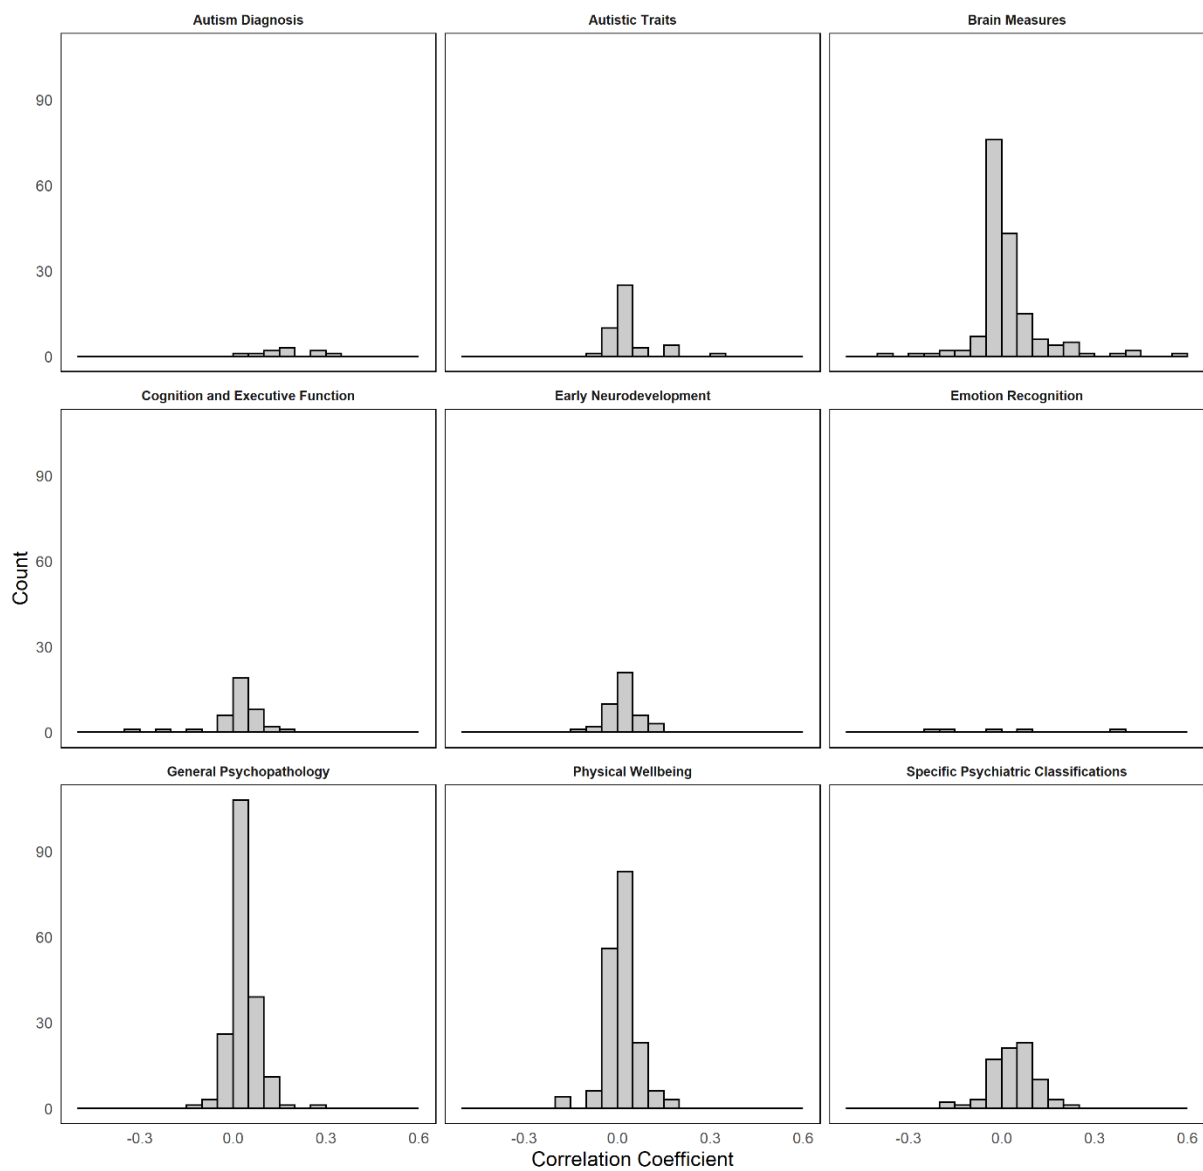

Outcome category	Rosenthal's fail-safe N
Autism diagnosis	39921
Autistic traits	1544
Other specific psychiatric classifications	95187
General psychopathology	90341
Cognition and executive function	1805
Physical wellbeing	30482
Early neurodevelopment	329
Emotion recognition	102
Brain measures	10733

sTable S5. Multi-level Meta-Analysis Results for Subcategories Specific Psychiatric Classifications – Secondary Results

Subcategory	<i>n</i> studies	<i>n</i> ind. Coh.	<i>n</i> est.	<i>r</i> _{Pooled} [95% CI]	<i>r</i> range	<i>P</i>	<i>I</i> ²		
							Total	Between-cohort	Within-cohort
ADHD	5	5	13	.049 [-.002 – .100]	-.03 – .110	.057	96.3%	84.5%	11.8%
Psychotic	4	4	18	.072 [.025 – .119]	-.031 – .213	.005	98.9%	72.7%	26.2%
Eating disorder	2	2	11	.005 [-.015 – .024]	-.038 – .058	.625	58.6%	0.0%	58.6%
Self-harm	3	3	18	.029 [-.076 – .135]	-.185 – .17	.564	99.7%	71.6%	28.1%
Other	7	5	18	.063 [.001 – .125]	-.117 – .199	.047	99.2%	24.7%	74.5%

NOTE. n studies = number of studies, n ind. Coh = number of independent cohorts the included studies are based on, n est = number of effect size estimates included
