## Supplementary Note

### Heritability of multi-organ imaging biomarkers

It has been shown that the CMR and brain MRI exists certain heritability by many twin and family studies<sup>1-3</sup>. However, the level of heritability might differ with respect to different heart or brain regions. For example, large brain volumes and cortical regions involved in language, executive function, and emotional regulations are usually consistently high in heritability<sup>1,4</sup>. Most of the brain structural MRI traits has relatively strong heritability, ranging from 0.6 to 0.8<sup>4</sup> compared with 0.2 to 0.6 heritability of brain functional connectivity<sup>5</sup>. Cardiac MRI traits are also heritable<sup>6</sup>, such as ascending aortic<sup>7</sup> and left ventricular structure<sup>8</sup>. The heritability of all abdominal IDPs is significant, which suggests that genetic differences account for a substantial portion of the variation among individuals. The inclusion of height and BMI as additional covariates has minimal impact on heritability. More detailed information about abdominal IDPs can be found in Liu, et al.<sup>9</sup>. All skeletal proportions are highly heritable (0.4-0.5) and the range in twin studies is between 0.4 and 0.8<sup>10</sup>.
