

Screening for Breast Cancer - Appendices

Update 2024

Table of Contents

Appendix 1 – PRISMA checklist.....	3
Appendix 2 - Database search strategy	6
Appendix 3 – Completed <i>PRESS</i> assessment.....	15
Appendix 4 – Portal submission.....	24
Appendix 5 – Grey literature search.....	34
Appendix 6 – DistillerSR screening forms	35
Appendix 7 – Data extraction form.....	37
Appendix 8 – GRADE summary of findings tables and forest plots	40
Table 1: Breast cancer mortality (RCTs, short-case accrual, stratified by age, over 10 years)	40
Table 2: Breast cancer mortality (RCTs, long-case accrual, stratified by age, over 10 years).....	44
Table 3: Breast cancer mortality (Observational studies, stratified by age, adherence to screen analysis over 10 years)	47
Table 4: Breast cancer mortality (Observational studies, stratified by age, stop screening analysis)	51
Table 5: Breast cancer mortality (Observational case-control studies, stratified by age)	52
Table 6: Breast cancer mortality (Quasi-experimental, sub-groups)	55
Table 7: All-cause mortality (RCTs, stratified by age, over 10 years)	58
Table 8: Stage at diagnosis (RCTs, all ages)	61
Table 9: Stage at diagnosis (Observational studies, all ages)	64
Table 10: Stage distribution of Breast Cancer (Quasi-experimental, Sub-groups)	65
Table 11: Overdiagnosis over 10 years (RCTs, stratified by age).....	68
Table 12: Overdiagnosis (Observational studies, stratified by age)	72
Table 13: Interval cancers (Intervention arm only - descriptive data of RCTs).....	74
Table 14: Treatment-related morbidity (RCTs, all ages)	81
Table 15: Treatment-related morbidity (Observational studies, all ages, adherence to screen analysis)	83
Table 16: Treatment-related morbidity (Observational studies, by age subgroup, stop screening analysis)	84
Table 17: Additional imaging (no cancer)	89

Appendix 9 – Cohort and RCT forest plot	93
Appendix 10 - Final Working Group Thresholds for GRADE	94
Appendix 11 - Working group survey for patient values and preferences towards screening for breast cancer	95
Appendix 12 – Baseline and lifetime risk calculations	102
Appendix 13 – List of excluded studies.....	104
Appendix 14 – Study characteristics table	120
Appendix 15 – Summary characteristics of RCTs (taken from previous 2017 review)	131
Appendix 16 – Risk of bias summary tables	132
Appendix 17 – Breast cancer mortality findings summary for exploratory analyses	137
Appendix 18 - Sensitivity analysis by RoB - Breast cancer mortality RCTs	139
Appendix 19 – Sensitivity analysis: Overdiagnosis RCTs removing high risk of bias trials	144
Appendix 20 – Supplementary data on additional imaging (no cancers)	147
Part A: Additional imaging (no cancer) resolved by imaging or biopsy per 1,000 screens from provincial sources	147
Part B: Additional imaging and biopsy (no cancer), per 1,000 screens.....	149
Part C: Additional imaging with or without biopsy (No Cancer) rate using 2019-2020 CPAC data, ages 40-49	150
Part D: Additional imaging with or without biopsy (No Cancer) using 2019-2020 CPAC data, ages 50-74	150
Part E: Additional imaging example calculations	150
Appendix 21 – Sensitivity analysis: Observational studies	152
Appendices References.....	154

Appendix 1 – PRISMA checklist

Section and Topic	Item #	Checklist item	Location where item is reported
TITLE			
Title	1	Identify the report as a systematic review.	1
ABSTRACT			
Abstract	2	See the PRISMA 2020 for Abstracts checklist.	3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of existing knowledge.	7
Objectives	4	Provide an explicit statement of the objective(s) or question(s) the review addresses.	7
METHODS			
Eligibility criteria	5	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	9
Information sources	6	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	11
Search strategy	7	Present the full search strategies for all databases, registers, and websites, including any filters and limits used.	Appendix
Selection process	8	Specify the methods used to decide whether a study met the inclusion criteria of the review, including how many reviewers screened each record and each report retrieved, whether they worked independently, and if applicable, details of automation tools used in the process.	11
Data collection process	9	Specify the methods used to collect data from reports, including how many reviewers collected data from each report, whether they worked independently, any processes for obtaining or confirming data from study investigators, and if applicable, details of automation tools used in the process.	12
Data items	10a	List and define all outcomes for which data were sought. Specify whether all results that were compatible with each outcome domain in each study were sought (e.g. for all measures, time points, analyses), and if not, the methods used to decide which results to collect.	13
	10b	List and define all other variables for which data were sought (e.g. participant and intervention characteristics, funding sources). Describe any assumptions made about any missing or unclear information.	13
Study risk of bias assessment	11	Specify the methods used to assess risk of bias in the included studies, including details of the tool(s) used, how many reviewers assessed each study and whether they worked independently, and if applicable, details of automation tools used in the process.	12
Effect measures	12	Specify for each outcome the effect measure(s) (e.g. risk ratio, mean difference) used in the synthesis or presentation of results.	13
Synthesis methods	13a	Describe the processes used to decide which studies were eligible for each synthesis (e.g. tabulating the study intervention characteristics and comparing against the planned groups for each synthesis (item #5)).	14
	13b	Describe any methods required to prepare the data for presentation or synthesis, such as handling of missing summary statistics, or data conversions.	14
	13c	Describe any methods used to tabulate or visually display results of individual studies and syntheses.	14
	13d	Describe any methods used to synthesize results and provide a rationale for the choice(s). If meta-analysis was performed, describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used.	14

Section and Topic	Item #	Checklist item	Location where item is reported
	13e	Describe any methods used to explore possible causes of heterogeneity among study results (e.g. subgroup analysis, meta-regression).	15
	13f	Describe any sensitivity analyses conducted to assess robustness of the synthesized results.	15
Reporting bias assessment	14	Describe any methods used to assess risk of bias due to missing results in a synthesis (arising from reporting biases).	15
Certainty assessment	15	Describe any methods used to assess certainty (or confidence) in the body of evidence for an outcome.	13
RESULTS			
Study selection	16a	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	20
	16b	Cite studies that might appear to meet the inclusion criteria, but which were excluded, and explain why they were excluded.	Appendix
Study characteristics	17	Cite each included study and present its characteristics.	20
Risk of bias in studies	18	Present assessments of risk of bias for each included study.	22
Results of individual studies	19	For all outcomes, present, for each study: (a) summary statistics for each group (where appropriate) and (b) an effect estimate and its precision (e.g. confidence/credible interval), ideally using structured tables or plots.	Appendix
Results of syntheses	20a	For each synthesis, briefly summarise the characteristics and risk of bias among contributing studies.	25-34
	20b	Present results of all statistical syntheses conducted. If meta-analysis was done, present for each the summary estimate and its precision (e.g. confidence/credible interval) and measures of statistical heterogeneity. If comparing groups, describe the direction of the effect.	25-34
	20c	Present results of all investigations of possible causes of heterogeneity among study results.	24
	20d	Present results of all sensitivity analyses conducted to assess the robustness of the synthesized results.	24
Reporting biases	21	Present assessments of risk of bias due to missing results (arising from reporting biases) for each synthesis assessed.	22
Certainty of evidence	22	Present assessments of certainty (or confidence) in the body of evidence for each outcome assessed.	25-34
DISCUSSION			
Discussion	23a	Provide a general interpretation of the results in the context of other evidence.	34
	23b	Discuss any limitations of the evidence included in the review.	39
	23c	Discuss any limitations of the review processes used.	39
	23d	Discuss implications of the results for practice, policy, and future research.	39
OTHER INFORMATION			
Registration and protocol	24a	Provide registration information for the review, including register name and registration number, or state that the review was not registered.	5
	24b	Indicate where the review protocol can be accessed, or state that a protocol was not prepared.	5

Section and Topic	Item #	Checklist item	Location where item is reported
	24c	Describe and explain any amendments to information provided at registration or in the protocol.	18
Support	25	Describe sources of financial or non-financial support for the review, and the role of the funders or sponsors in the review.	2
Competing interests	26	Declare any competing interests of review authors.	2
Availability of data, code and other materials	27	Report which of the following are publicly available and where they can be found: template data collection forms; data extracted from included studies; data used for all analyses; analytic code; any other materials used in the review.	2

Date submitted: 2023 Jul 5 Date requested by: 2023 Jul 7

1. Systematic Review Title

Screening for breast cancer: An evidence review to inform the update the Canadian Task Force on Preventive Health Care guideline

2. This search strategy is ...

X	My PRIMARY (core) database strategy — First time submitting a strategy for search question and database
	My PRIMARY (core) strategy — Follow-up review NOT the first time submitting a strategy for search question and database. If this is a response to peer review, itemize the changes made to the review suggestions
	SECONDARY search strategy— First time submitting a strategy for search question and database
	SECONDARY search strategy — NOT the first time submitting a strategy for search question and database. If this is a response to peer review, itemize the changes made to the review suggestions

3. Database (e.g., MEDLINE, CINAHL)

MEDLINE

4. Interface (e.g., Ovid, EbscoHost...)

Ovid

5. Research Question (Describe the purpose of the search) [mandatory]

This evidence review aims to address the following three key questions (KQs):

1. a) What are the benefits and harms of different mammography-based screening strategies compared to no screening in adults greater than 40 years of age and not at high risk for breast cancer?
 - b) Do the benefits and harms differ by population characteristics and risk markers (e.g., age, breast density, race/ethnicity, family history)?
2. a) What are the comparative benefits and harms of different mammography-based breast cancer screening strategies in adults greater than 40 years of age and not at high risk for breast cancer?
 - b) Do the comparative benefits and harms differ by population characteristics and risk markers (e.g., age, breast density, race/ethnicity, family history)?
3. How do patients weigh the benefits and harms of breast cancer screening?

6. PICO Format Outline the PICOs for your question — i.e., Patient, Intervention, Comparison, Outcome, and Study Design — as applicable

P	Adults with female sex-specific breast tissue aged ≥40 years of age and not at high-risk for breast cancer Specific populations (using within and between-study data where able): <ul style="list-style-type: none"> • Age (40-44 years, 45-49 years, 50-69 years, 70-74 years, 75 and older) • Ethnicity, especially Indigenous and Black populations • Socioeconomic status • Geographical location (rural vs. urban settings) • Breast density (i.e., extremely [e.g., BIRADS category D] vs not extremely dense breasts; other comparisons).
I/ Exposure	Adults with female sex-specific breast tissue aged ≥40 years of age and not at high-risk for breast cancer Specific populations (using within and between-study data where able): <ul style="list-style-type: none"> • Age (40-44 years, 45-49 years, 50-69 years, 70-74 years, 75 and older) • Ethnicity, especially Indigenous and Black populations • Socioeconomic status

	<ul style="list-style-type: none"> • Geographical location (rural vs. urban settings) • Breast density (i.e., extremely [e.g., BIRADS category D] vs not extremely dense breasts; other comparisons.
C	
O	<p>Benefits (reductions)</p> <ol style="list-style-type: none"> 1. Breast cancer mortality 2. All-cause mortality 3. Advanced-stage disease (stage III/IV) (including one of (hierarchy): stage III + IV disease; size ≥ 50 mm, 4+ positive lymph nodes) 4. Stage II or higher (including one of (hierarchy): Stage II+, size ≥ 20 mm, 1+ positive lymph node) 5. Treatment-related morbidity (i.e. invasiveness of treatment e.g., less invasive surgeries, need for chemotherapy [early vs. advanced disease]) 6. Breast cancer morbidity (e.g., adverse effects of treatment, physical/functional impairment) 7. Detection of invasive cancer <p>Harms (7-14 are proportions/# with 1+)</p> <ol style="list-style-type: none"> 8. Overdiagnoses^c 9. Detection of DCIS (cumulative) 10. False-positive screens (single round) 11. False-positive screens (cumulative over multiple rounds) 12. Biopsies on false-positives^d (single round) 13. Biopsies on false positives (cumulative over multiple rounds) 14. Interval cancers (includes FNs and clinically detected CAs before next screen or time equivalent) 15. False negatives 16. Incidental findings (if using MRI or ultrasound)
S	<p>All outcomes</p> <ol style="list-style-type: none"> 1. Randomized controlled trials, including cluster 2. Non/quasi-randomized controlled trials 3. Prospective or retrospective observational studies of large screening cohorts with a concurrent control group (including controlled before-after studies) (i.e., all having exposure data at the individual level and linked with outcomes) 4. If reporting data specific to key demographic groups (i.e., 40-49 and/or 70+ years, race/ethnicity group): ecological/population-based (e.g., exposure data not at participant level, over multiple years), time trend/series and before-after studies

7. Inclusion Criteria (List criteria such as age groups, study designs, etc., to be included) *[optional]*

2014 – present

9. Exclusion Criteria (List criteria such as study designs, date limits, etc., to be excluded)

10. Was a search filter applied? Yes

If YES, which one(s) (e.g., Cochrane RCT filter, PubMed Clinical Queries filter)? Provide the source if this is a published filter.
[mandatory if YES to previous question — textbox]

Cochrane HSSS, 2008 – sensitivity and specificity-maximizing version with slight adjustments
Other design filters derived from CADTH's

11. Notes or comments you feel would be useful for the peer reviewer *[optional]*

Limited time available for this review so important to contain volume where possible. We are including accepted design filters and overlaying this with the outcomes/benefits/harms of interest.

Team has noted they do not want male-only population removed.

Not interested in breast self-examination or physical examination unless included as part of mammography screening.

12. Please copy and paste your search strategy here, exactly as run, including the number of hits per line. [mandatory]

Peer review assessment: this section to be filled in by the reviewer

Reviewer: Kaitryn Campbell

Email: campbell.information.consulting@gmail.com

Date completed: 6 Jul 2023

Do you wish to be acknowledged? (If yes, the review team will be advised to add an acknowledgement to any publications related to this work).
Yes please.

The suggested acknowledgement is "We thank Kaitryn Campbell, MLIS, MSc for peer review of the Medline search strategy."

1. TRANSLATION

A ---No revisions	X
B --- Revision(s) suggested	
C --- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

2. BOOLEAN AND PROXIMITY OPERATORS

A ---No revisions	X
B --- Revision(s) suggested	
C --- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

3. SUBJECT HEADINGS

A ---No revisions	
B --- Revision(s) suggested	X
C --- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

Line 37, consider doing same thing as you did with Line 34: (case reports not (case reports and randomized controlled trial)).pt., because Case Reports + RCT as publication types exist

For Benefits/Harms Concept, consider adding exp Neoplasm Metastasis/ with appropriate free text terms.

4. TEXT WORD SEARCHING

A ---No revisions	
B --- Revision(s)suggested	X
C --- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

As a synonym everywhere “harm” etc. appear, consider adding: side-effect* OR sideeffect*

Line 93-96, consider adding “prevent*” to (avoid* or declin* or decreas* or lessen* or lower* or reduc*)

Line 97, should “mis-detection” be “mis-detect*”?

Lin 99, consider hyphenating all the following terms: undetected or undiagnos* or unidentif*

Line 104, consider hyphenating: overtreat*

Line 105, consider hyphenating all the following terms: overuse? or overusing or overutilis* or overutiliz*

Line 107, consider hyphenating all the following terms: undesirabl* or unintent* or unintent* or unsafe* or unwanted –also see lines 108 & 109 for all terms mentioned above and consider hyphenating

5. SPELLING, SYNTAX, AND LINE NUMBERS

A --No revisions	X
B -- Revision(s)suggested	
C -- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

6. LIMITS AND FILTERS

A --No revisions	X
B -- Revision(s) suggested	
C -- Revision(s) required	

If “B” or “C,” please provide an explanation or example:

OVERALL EVALUATION (Note: If one or more “revision required” is noted above, the response below must be “revisions required”.)

A --No revisions	
B -- Revision(s) suggested	X
C -- Revision(s) required	

Additional comments:

Nicely done. I’ve made a number of minor comments for your consideration.

Appendix 6 – DistillerSR screening forms

Level 1 – Title and abstract screening

1. After reviewing the PICO criteria, is this study eligible for inclusion?
 - Yes
 - No

Instructions in Distiller for exclusions:
At this stage please exclude: <ul style="list-style-type: none">● The following populations:<ul style="list-style-type: none">● <u>All</u> participants are considered high-risk (e.g., selected on the basis that they all have BRCA1 gene or family history of cancer)● The following study designs:<ul style="list-style-type: none">● Cross-sectional studies● Modelling studies (e.g., prediction models, nomograms, simulation studies)● Diagnostic accuracy studies (e.g., measuring sensitivity, specificity of a tool)● Studies focusing on behaviours, attitudes, or preferences of screening.● Narrative reviews, editorials, commentaries, case reports● Protocols● The following interventions:<ul style="list-style-type: none">● Mammography for diagnosis or imaging● Screening with clinical breast examination or breast self-examination <u>alone</u>● Screening with MRI or ultrasound <u>alone</u>
Note: <p>Ensure that the participants enrolled into the study that are included based on a breast cancer diagnosis have been linked back to being screen- or not screen-detected cancer.</p> <p>For references without abstracts, we will exclude, <u>unless</u> you can infer from the title that it is clearly a breast cancer screening study.</p>

Level 2 – Full-text screening

1. Is the language of publication English or French?
 - Yes (**include**)
 - No (**exclude**)
2. Please select the study design (*drop down menu*)
 - Randomized or quasi-randomized controlled trial (**include**)
 - Non-randomized controlled trial (published ≥2014) (**include**)
 - Cohort study (published ≥2014) (**include**)
 - Case-control study (published ≥2014) (**include**)
 - Controlled before and after study (published ≥2014) (**include**)

- Time trend/series (published ≥ 2014) **(include)**
 - Ecological (population-based) study (published ≥ 2014) **(include)**
 - Review (including systematic, scoping, and narrative reviews) **(exclude)**
 - Observational study (published < 2014) **(exclude)**
 - Abstract or conference proceeding **(exclude)**
 - Protocol **(exclude)**
 - Other **(exclude)**
3. Do any of the following criteria below apply to the study?
- Participants are younger than 40 years of age **(exclude)**
 - Participants are at high risk of breast cancer (personal or family history of breast or ovarian cancer, significant genetic markers such as BRCA1/BRCA2 or Li-Fraumeni syndrome) **(exclude)**
 - Study uses a screening strategy other than mammography **(exclude)**
 - Ineligible comparator (must be a "no screened group") **(exclude)**
 - Breast imaging or clinical examinations were conducted for diagnosis or surveillance **(exclude)**
 - Not a primary care setting **(exclude)**
 - Screening initiation date < 2000 **(exclude)**
 - Does not include any outcomes of interest **(exclude)**
 - None of the above **(include)**
4. Please select which country the study was conducted from the list below (*drop down menu*)
Countries that were considered "Very High" on the HDI were included; all others were excluded at this stage.

Typically, these questions are nested. If an answer is an include (as indicated), the form allows us to proceed to the next question. If an answer was an exclude, the form would end, and that reference would be excluded for that reason.

Appendix 7 – Data extraction form

Level 3 – Data Extraction

First Tab – Summary Characteristics

**Green items can be pulled from Distiller Datarama report and responses to level 2 responses*

Study identification

1. *First author*
2. *Year of publication*
3. *Name of journal/source document*
4. *Country*

Study characteristics

5. Study aim
6. *Type of study/study design*
 - a. If cohort study, specify
 - i. Screened vs unscreened [SU]
 - ii. Offered screening vs not [ON]
 - iii. Adhered to screening vs offered but not attended [OA]
 - iv. Not applicable [NA]
7. Trial name or database (e.g., CNBSS, SEER)
8. Total study period
9. Dates of screening
10. Screening initiation date prior to and after 2000? (yes/no)
11. Duration of follow-up

Population details

12. Population details (*Provide brief details on the population studied, copy and pasted from the text is acceptable (e.g., age of participants enrolled, existing comorbidities) otherwise type NR*)
13. Total number of participants
14. Mean or median age at entry
15. Recruitment method (*Details on how the population was selected (e.g., Registry, Claims database, etc.)*)
16. Eligibility criteria
17. Other populations studied (e.g., ethnic groups, LGBTQ+, disability)
18. Population health status (*Details on any comorbidities, family history of BC, history of other cancers*)

Control group (not exposed)

19. Name of the control/not exposed group
20. Concurrent or historical control?
21. Control group details

22. Total number of participants in the control group
23. Total number in the control group received/not exposed (*Number of participants who received the control (after exclusions, for example)*)
24. Number lost to follow-up (if applicable)
25. Number excluded (if applicable)
26. Reasons for exclusions or lost to follow-up

Intervention group (exposed)

27. Name of the intervention/exposed group (e.g., type of screening test)
28. Type of mammography received
29. Number of screening intervals
30. Duration of screening interval
31. Intervention/exposed group details as reported (e.g., screening interval, number of screening rounds)
32. Total number of participants in the intervention/exposed group
33. Number lost to follow-up (if applicable)
34. Number excluded (if applicable)
35. Reasons for exclusions or lost to follow-up

Level 3 – Data Extraction

Second Tab – Outcome Data

Outcome data

1. Relevant outcomes evaluated*

**We will extract absolute values (total numbers and percentages, n%), odds ratios (OR), relative risks (RR), hazard ratios (HR), standard deviations (SD) and confidence intervals (CI). We will also report on any adjusted variables.*

Outcomes of interest:

Benefits (reductions)

- i. Breast cancer related mortality
- ii. All-cause mortality
- iii. Treatment-related morbidity, measured by:
 - a. Receipt of radiotherapy (yes/no)
 - b. Receipt of chemotherapy (yes/no)
 - i. Subgroup by anthracycline vs no anthracycline
 - c. Type of surgery: complete mastectomy vs partial mastectomy/lumpectomy
 - d. Surgical management of axilla (axial lymph node dissection [ALND] vs sentinel lymph node biopsy [SLNB])
- iv. Stage distribution of breast cancer
 - a. Stage II and higher
 - b. Stage III and higher
 - c. Stage IV

- v. Breast cancer morbidity (e.g., adverse effects of treatment, physical/functional impairment). Measured using composite scores from different scales

Harms

- vi. Overdiagnoses (We will calculate the number of excess diagnoses from prospective data with at least 10 years of follow up from the time of enrollment over 1,000 persons screened).
- vii. Additional imaging +/- biopsy (cumulative over multiple rounds)
- viii. Additional imaging+ biopsy (cumulative over multiple rounds)
- ix. Interval cancers (includes false negatives and clinically detected cancers before next screen or time equivalent)
 - a. Subgroup by Invasive vs DCIS

Benefit or harm

- x. Health related quality of life (secondary outcome)
- xi. Life years gained (or lost)

Study findings

2. Overall study conclusions
3. Reported limitations

Appendix 8 – GRADE summary of findings tables and forest plots

Table 1: Breast cancer mortality (RCTs, short-case accrual, stratified by age, over 10 years)

Mammography +/- CBE compared to Usual Care							
Outcomes	Absolute effects		Relative effect (95% CI) §	No of participants (studies) *	Quality of the evidence (GRADE) Clinical threshold of 0.5	Quality of the evidence (GRADE) Clinical threshold of 1	Comments
	Risk with Usual Care (Assumed Risk) ‡	Absolute effect (95% CI)					
Sub-Group: Breast-Cancer Mortality (40-49 years) # Randomised: Unclear # Analyzed: Unclear Range of follow-up (yrs): 17.7 to 25.7	General population		RR 0.85 (0.78 to 0.93)	Unavailable (8 ^{1-3, 5-7, 9-10} RCTs) ^a	⊕⊕○○ LOW ^{b,c,d,e,f}	⊕⊕○○ LOW ^{b,c,d,e,f}	Using a threshold of 0.5 or 1 fewer deaths per 1,000, screening may make little to no difference in reducing breast cancer mortality over 10 years for individuals aged 40 to 49 years in a general population.
		0.27 fewer per 1,000 (from 0.13 fewer to 0.40 fewer)					
		1.8 per 1,000					
	Moderately increased risk Based on family history (scaled adjustment)						
	0.44 fewer per 1,000 (0.20 fewer to 0.64 fewer)	2.9 per 1,000			Using a threshold of 1 fewer death per 1,000, screening may make little to no difference in reducing breast cancer mortality over 10 years for individuals aged 40 to 49 years at moderately increased risk for breast cancer.		
	Moderately increased risk Based on dense breasts (scaled adjustment)				⊕○○○ VERY LOW ^{b,c,d,f,g}	⊕⊕○○ LOW ^{b,c,d,e,f}	Using a threshold of 0.5 fewer deaths per 1,000, we are very uncertain whether screening decreases breast cancer mortality over 10 years for individuals aged 40 to 49 at moderately increased risk for breast cancer.
		0.53 fewer per 1,000 (0.25 fewer to 0.77 fewer)					Using a threshold of 1 fewer death per 1,000, screening may make little to no difference in reducing breast cancer mortality over 10 years for individuals aged 40 to 49 years at moderately increased risk for breast cancer.

	11.6 per 1,000	1.74 fewer per 1,000 (0.81 fewer to 2.55 fewer)					

‡The baseline risk represents the breast cancer mortality rate over 10 years in an unscreened group based on observational data reported by Coldman et al.¹ To calculate a moderately increased risk group due to family history, we used an estimate from Engmann et al.² suggesting that having a first degree relative increases the lifetime risk by 1.6 times and multiplied the general population risk estimate by 1.6. To calculate a moderately increased risk group due to dense breasts, we used an estimate from the Swedish mammography trial which suggested those with high breast density have a relative increased lifetime risk of 1.9.³

§ The relative effect is based on our previous systematic review and guideline⁴ where a subgroup analysis of relative risk by age was assessed and no difference in RR among subgroups was detected and true differences resulting from age were deemed unlikely. Therefore, we used the RR for all ages rather than focusing on each decade of age as we had previously done in our 2018 guideline.

*The number of participants and studies reflect the previous analysis for each age decade, rather than the number of studies that are included in the relative effect estimate for all ages.

CI: Confidence interval; RR: Risk ratio

Bibliography: 1: Gothenburg (Nystrom 2016⁵), 2: Age (Moss 2015⁶), 3: Swedish Two County (Kopparberg & Ostergotland) (Tabar 2011⁷), 4: Malmo I (Nystrom 2016⁵), 5: Malmo I (Nystrom 2002⁸), 6: Malmo II (Nystrom 2016⁵), 7: CNBSS 1 (Miller 2014⁹), 8: CNBSS 2 (Miller 2014⁹), 9: HIP (Shapiro 1988¹⁰), 10: Stockholm (Nystrom 2016⁵), 11: Stockholm (Nystrom 2002⁸)

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

a. Two studies considered quasi-randomised (Stockholm & Gothenburg).

b. Randomisation and allocation concealment were either not reported or there were serious deficiencies in these areas, therefore we rated down once for risk of bias. A sensitivity analysis by risk of bias is presented in Supplemental Material, Appendix 1 and no differences in relative risk were detected between high risk and moderate risk of bias papers. True differences resulting from risk of bias were deemed unlikely, however we still rated down once due to concerns with risk of bias impacting the overall estimate.

c. All point estimates in our pooled analysis lie to one side of our threshold. We did not rate down for inconsistency.

d. Breast density was not addressed. Studies reported in Nystrom 2002 and Nystrom 2016 included one round of screening in the control group as part of the short-case accrual calculation. Therefore, the study estimates may be underestimated (a larger benefit from the intervention may be possible). Data are from trials initiated in the 1960s-1990s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect may differ if applied to today's Canadian screening context. There are no high-quality clinical trials examining the impact of screening on breast cancer screening deaths using contemporary screening methods. We downrated once for indirectness.

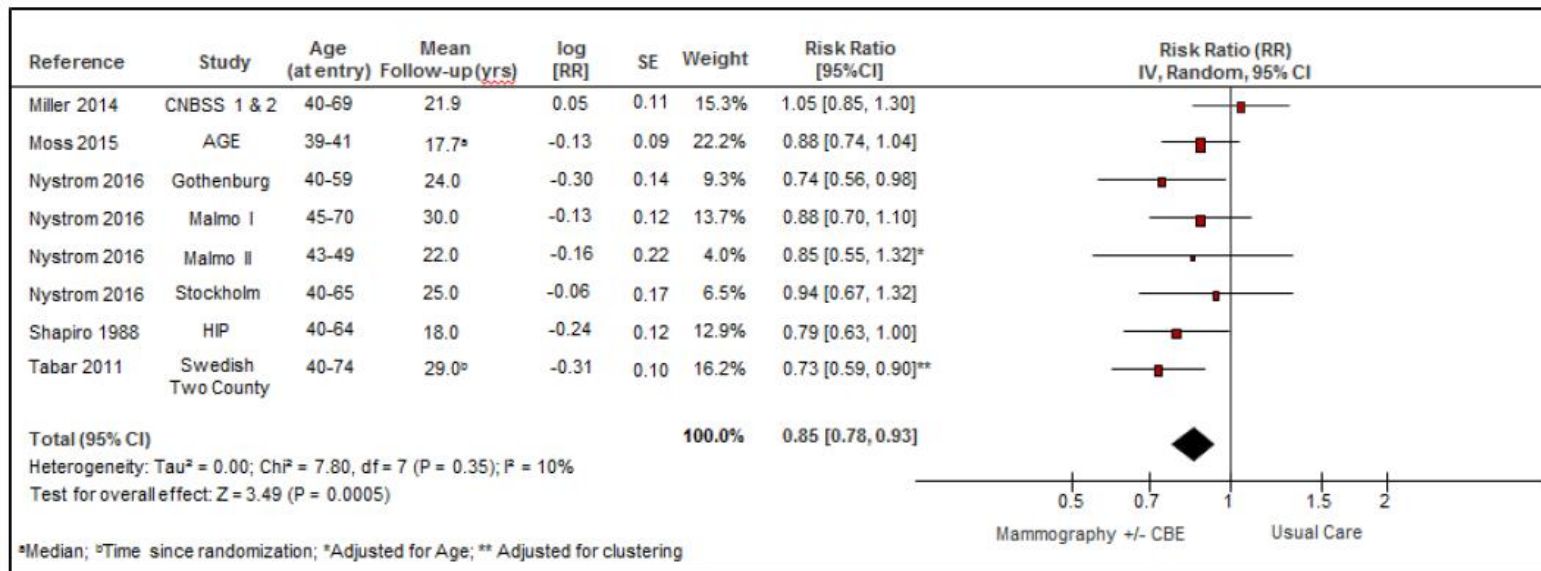

e. Given the large sample size; an optimal sample size calculation was not warranted. The 95% CI does not cross the clinical decision threshold; therefore, we did not rate down for imprecision.

f. According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

g. Given the large sample sizes; an optimal sample size calculation was not warranted. The 95% CI crosses the clinical decision threshold; therefore, we rated down once for imprecision.

h. Approximately half of the point estimates in our pooled analysis lie on either side of our threshold. We rated down once for inconsistency.

	11.6 per 1,000	6.03 fewer per 1,000 (4.99 fewer to 6.84 fewer)					

‡The baseline risk (in the control group) was not representative of all included studies. Numerators and/or denominators were either unclear or not reported for some studies. For the age subgroup calculations, the baseline risk for each age group was taken from the Coldman cohort study.

*Studies varied between film and digital mammography.

**Pooling was performed for a screening adherence analysis. To note that Coldman reported a standardized mortality ratio (SMR) however, it has been noted in the literature that an SMR can approximate a RR when the mortality rate in the control group is less than 10 per 1000 for a one-year period in a 10-year age band (Symons and Taubee, 1981). The statistical heterogeneity of this estimate is high ($I^2=94\%$). Other sensitivity analyses for combining these four studies are provided in Supplemental KQ1 GRADE Material, Appendix 3.

CI: Confidence interval; RR: Risk ratio

Bibliography: 1: Choi 2021¹⁵, 2: Coldman 2014¹⁶, 3: Duffy 2021¹⁷, 4: Morrell 2017¹⁸

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

- We rated down once for the lack of adjustment for important confounding factors across studies, including use of hormone replacement therapy, socioeconomic status, or other adjustment for self-selection bias. Lack of reporting or measurement of population at increased risk of breast cancer (Duffy, Morell). Studies did not report average follow-up length and reasons for loss to follow-up are not reported (Duffy, Morell).
- Heterogeneity is very high across studies ($I^2=94\%$); ($p\text{-value}<0.0001$). Estimates from studies included rate ratios, risk ratios and standardized mortality ratios, with varying degrees of adjustment for confounding factors. We are unable to explain the high statistical heterogeneity through sensitivity analyses (Supplemental KQ1 GRADE Material, Appendix 3), however, all individual estimates point to a reduction in BC mortality. Similarly, all point estimates in our pooled analysis lie to one side of our threshold, therefore we did not rate down for inconsistency.
- We did not rate for indirectness as both the studies (Duffy and Coldman) are population-based studies representing general population..

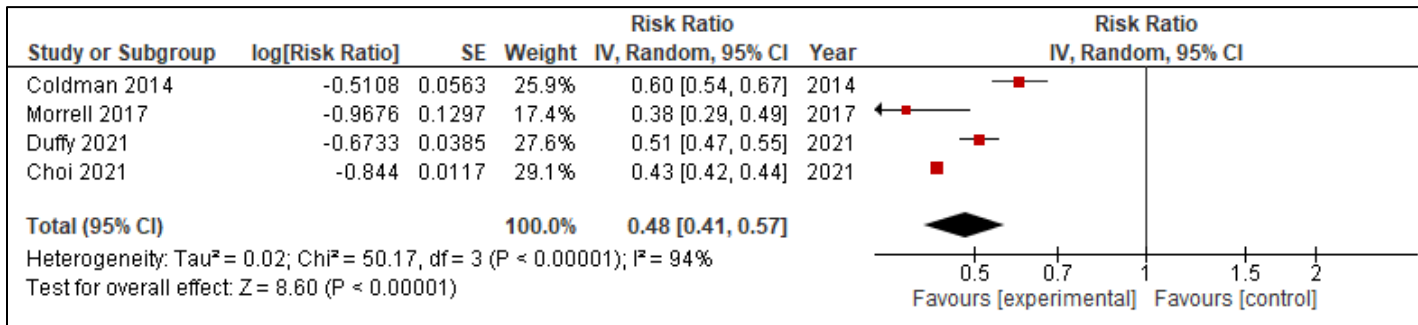

d. The 95% CI does not cross the clinical decision threshold; therefore, we did not rate down for imprecision.

e. The 95% CI crosses the clinical decision threshold; therefore, we rated down once for imprecision.

f. We did not rate up for the magnitude of effect because not all plausible confounders (e.g., age, hormone replacement therapy, breast density, elevated risk), were adjusted for, decreasing our confidence in the estimated effect. Following GRADE guidance, the RR is on the threshold of being considered a large effect (i.e., RR either >2.0 or <0.5 based on consistent evidence from at least 2 studies, with no plausible confounders).

g. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

Table 3 forest plot

All adherence to screen papers: Coldman, Morrell, Duffy, Choi. The cohort adherence to screen: Morrell reported BC mortality for ever screened cohort (control group is never screened).

Table 4: Breast cancer mortality (Observational studies, stratified by age, stop screening analysis)

“Continue Screening” After Baseline Examination compared to “Stop Screening” After Baseline Examination

Outcomes	Absolute effects		Hazard ratio (95% CI)	No of participants (studies)	Quality of the evidence (GRADE) Clinical threshold of 0.5	Quality of the evidence (GRADE) Clinical threshold of 1	Comments
	Baseline risk with stopping screening	Absolute effect (95% CI)					
Sub-Group: Breast-Cancer Mortality (70-74 years)	General population		HR 0.78 (0.63 to 0.95)	1235459 (1 study ¹)	⊕○○○ VERY LOW ^{a,b,c,d,e}	⊕○○○ VERY LOW ^{a,b,c,d,e,g}	Using a threshold of 0.5 or 1 fewer deaths per 1,000, we are very uncertain whether continuing screening decreases breast cancer mortality over 10 years for individuals aged 70 to 74 years in a general population.
# of follow-up (yrs): 8.0	3.7 per 1,000	0.81 fewer per 1,000 (from 0.19 to 1.37 fewer)					
Sub-Group: Breast-Cancer Mortality (75-84 years)	General population		HR 1.00 (0.83 to 1.19)	1403735 (1 study ¹)	⊕○○○ VERY LOW ^{a,b,c,d,e}	⊕⊕○○ LOW ^{a,b,c,f,e,g}	Using a threshold of 0.5 fewer deaths per 1,000, we are very uncertain whether continuing screening decreases breast cancer mortality over 10 years for individuals aged 75 to 84 years in a general population. Using a threshold of 1 fewer death per 1,000, continuing screening may make little to no difference in reducing breast cancer mortality over 10 years for individuals aged 75 to 84 years in a general population.
# of follow-up (yrs): 8.0	3.7 per 1,000	0.0 fewer per 1,000 (from 0.63 fewer to 0.70 more)					

CI: Confidence interval; HR: Hazard ratio

Bibliography: 1: Garcia-Albeniz 2020¹⁹

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

a. We did not downrate for risk of bias. Study was judged to be of moderate quality using the JBI critical appraisal tool for cohort studies.

b. We did not downrate for inconsistency (only one study included).

c. We did not downrate for indirectness. The study answers the question of stopping versus continuing screening and all patients have received at least one baseline mammography.

d. The 95% CI crosses the clinical decision threshold; therefore, we rated down once for imprecision.

e. We did not rate up for the magnitude of effect because the effect size did not meet the threshold for uprating. Following GRADE guidance, the RR is on the threshold of being considered a large effect (i.e., RR either >2.0 or <0.5 based on consistent evidence from at least 2 studies, with no plausible confounders).

f. The 95% CI does not cross the clinical decision threshold and we did not rate down for imprecision.

g. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

	Moderately increased risk Based on dense breasts (scaled adjustment)				⊕○○○ VERY LOW a,b,c,d,e,f	⊕○○○ VERY LOW a,b,c,d,e,f	Using a threshold of 0.5 or 1 fewer deaths per 1,000, we are very uncertain whether screening decreases breast cancer mortality over 10 years for individuals aged 70 to 74 years at a moderately increased risk for breast cancer.
	11.6 per 1,000	5.10 fewer per 1,000 (4.18 fewer to 5.92 fewer)					

‡The baseline risk represents the breast cancer mortality rate over 10 years in an unscreened group based on Canadian observational data reported by Coldman et al.¹ To calculate a moderately increased group risk, we used an estimate from Engmann et al.² suggesting that having a first degree relative increases the lifetime risk by 1.6 times and multiplied the general population baseline risk estimate by 1.6.

*Studies varied between film and digital mammography.

**Absolute risks were calculated using odds ratios (all adherence to screen exposure).

CI: Confidence interval; OR: Odds ratio

Bibliography: 1:Paap 2014²⁰, 2: Pocobelli 2015²¹, 3. Massat 2016²², 4: Ripping 2017²³, 5. van der Waal 2017²⁴, 6. Maroni 2021²⁵, 7. De Troeyer 2023²⁶

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

a. We rated down once for risk of bias. Cases and controls were not age matched (De Troeyer and van der Waal) or failed to adjust for important confounding factors related to self-selection bias (De Troeyer, Maroni, Van der Waal, Massat, Pocobelli, Paap and Ripping). Several studies did not provide screening details or confirm all women were invited to screening (Massat, Pocobelli, Paap, Ripping). Average follow-up length not clearly reported across studies.

b. All individual estimates point to a reduction in BC mortality, so we did not downgrade for inconsistency.

c. We did not downgrade for indirectness since the studies used population-based approach and are reflective of general population.

- d. Given the large sample sizes; an optimal sample size calculation was not warranted. The 95% CI does not cross the clinical decision threshold; therefore, we did not rate down for imprecision.
- e. We did not rate up for the magnitude of effect because not all plausible confounders (e.g., age, hormone replacement therapy, breast density), were adjusted for, decreasing our confidence in the estimated effect. Following GRADE guidance, the RR is not considered a large effect (i.e., RR either >2.0 or <0.5 based on consistent evidence from at least 2 studies, with no plausible confounders).
- f. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

D: Wilkinson 2023³⁰

Explanations

- We did not downrate for RoB. Study assessed at low risk of bias (RoB score for JBI Quasi-experimental tool=7/9). Study reported no data on reliability of outcomes and average follow-up period.
- We downrated once for RoB. Study at moderate risk of bias (RoB score for JBI Quasi-experimental tool=5/9). Different number of participants across comparative groups. No information on lost to follow-up participants. No data on reliability of outcome measures.
- We downrated once for RoB. Study at moderate risk of bias (RoB score for JBI Quasi-experimental tool=6/9). No information on control group, loss-to follow-up patients and reliability of outcome measures
- We did not downrate for RoB. Study at low risk of bias (RoB score for JBI Quasi-experimental tool=7/9). Noted that there may be differences in the participants and access to care/treatment across screening and non-screening jurisdictions beyond screening that could impact survival differences.
- Unable to evaluate imprecision using thresholds, as the baseline rates were not available to allow the calculation of absolute effects. Therefore, a minimally contextualized approach was used. The total population is large (>2000) and there is a large event rate (>300). We did not downrate for imprecision.
- Not downrated for inconsistency. Single study evaluated outcome (unable to evaluate heterogeneity).
- Downrated once for indirectness. Pre-screening periods ranged across studies between 1958 and 2004. There are population-level differences that may affect mortality beyond the introduction of mammography screening between the pre-screening period and the post-screening period.
- Downrated once for indirectness. Study assessed the effect of screening programs on outcomes of interest, rather than the effect of individual-level mammography screening. Not all women in screening jurisdictions participated in screening and it is unknown if BCs were diagnosed by screening or through other means (e.g., interval cancers, symptoms).

‡The baseline risk has been calculated using deaths and age-specific mortality rates data from Statistics Canada and estimated over a 10-year period. (<https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=1310039201&pickMembers%5B0%5D=2.11&pickMembers%5B1%5D=3.3&cubeTimeFrame.startYear=2017&cubeTimeFrame.endYear=2021&referencePeriods=20170101%2C20210101>)

§ Following the same logic as breast cancer mortality, the relative effect is based on our previous systematic review and guideline⁴ where a subgroup analysis of relative risk by age was assessed and no difference in RR among subgroups was detected and true differences resulting from age were deemed unlikely. Therefore, we used the RR for all ages rather than focusing on each decade of age as we had previously done in our 2018 guideline.

*The number of participants and studies reflect the previous analysis for each age decade, rather than the number of studies that are included in the relative effect estimate for all ages.

6: CNBSS 1 (Miller 2002³³)

Explanations

a. Two studies considered quasi-randomised (Stockholm & Gothenburg)

b. Randomisation and allocation concealment were either not reported or there were serious deficiencies in these areas, we downrated once for risk of bias.

c. All point estimates in our pooled analysis lie to one side of our threshold. We did not rate down for inconsistency.

d. Breast density was not addressed. For some studies, the control group received screening after the screening period. Studies reported in Nystrom 2002 and Nystrom 2016 included one round of screening in the control group as part of the short-case accrual calculation. Therefore, the study estimates may be underestimated (a larger benefit from the intervention may be possible). Downrated once for indirectness. Data are from trials initiated in the 1960s-1990s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect may differ if applied to today's Canadian screening context. There are no high-quality clinical trials examining the impact of screening on breast cancer screening deaths using contemporary screening methods.

e. Not downrated for imprecision i) The number of events and total population are large (>300 threshold for events); and (ii) the 95% CIs include the null, but do not cross clinical decision threshold (1 fewer or 1 more). Given the large sample sizes, an optimal sample size calculation was not warranted.

f. According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

g. Downrated once for imprecision. i) The number of events and total population are large (>300 threshold for events); and (ii) the 95% CIs include the null and cross the clinical decision threshold (1 fewer or 1 more). Given the large sample sizes, an optimal sample size calculation was not warranted.

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

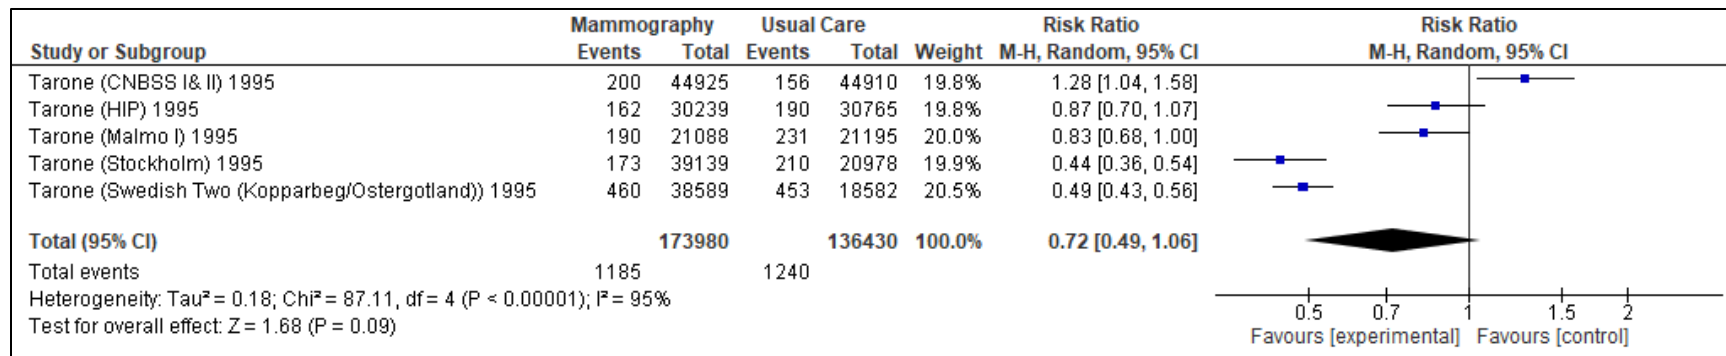

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

- a. One study considered quasi-randomised (Stockholm)
- b. Downrated once for risk of bias. Randomisation and allocation concealment were either not reported sufficiently (Malmö I, HIP) or there were serious deficiencies in these areas (CNBSS-I, Stockholm).
- c. Approximately half of the point estimates in our pooled analysis lie on either side of our threshold. We rated down once for inconsistency.
- d. Data are from trials initiated in the 1960s-1990s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect may differ if applied to today's Canadian screening context. There are no high-quality clinical trials examining the impact of screening on breast cancer screening deaths using contemporary screening methods.
- e. Downrated once for imprecision. CI crosses threshold for benefit of breast cancer screening for proportion of patients diagnosed at stage II or higher.
- f. Downrated once for risk of bias. High risk of bias due to concerns with randomisation method and allocation concealment (CNBSS I).
- g. Not downrated for inconsistency. Single study evaluated outcome.
- h. Downrated once for imprecision. Low number of events (fewer than 300) and confidence interval crosses threshold for harm.
- i. Downrated once for risk of bias. High risk of bias due to risk of bias in randomization and allocation concealment (Stockholm) and use of local endpoint committee for blinding of outcomes (HIP).
- j. All point estimates in our pooled analysis lie to one side of our threshold. We did not rate down for inconsistency.
- k. Did not downrate for imprecision. Large population and CI does not cross below the threshold for benefit of breast cancer screening for proportion of population diagnosed at stage III.
- l. According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

Table 8 forest plots

Breast Cancer Diagnosis at stage II or higher

Breast Cancer Diagnosis at stage III or higher

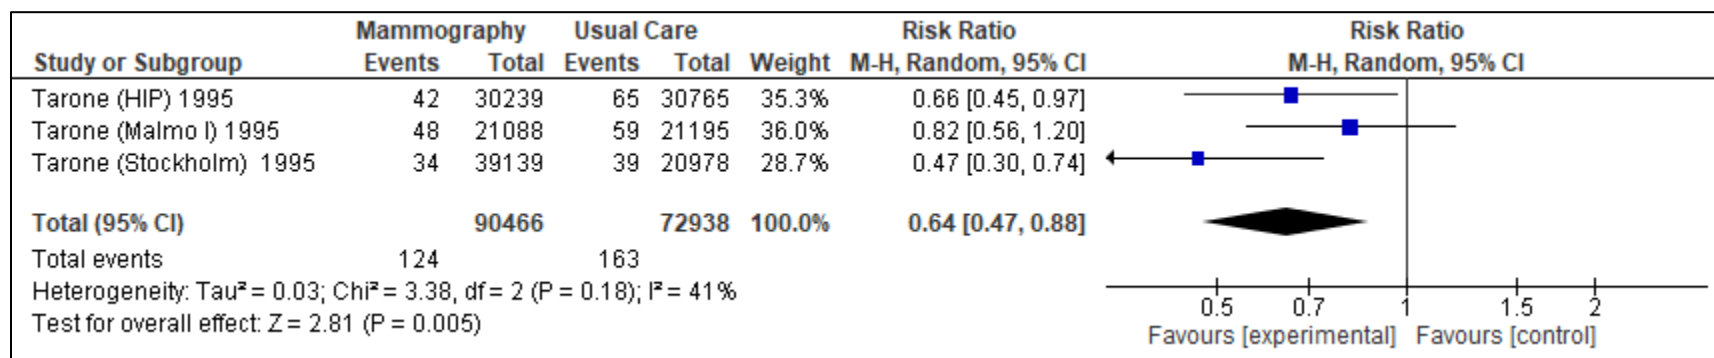

Table 9: Stage at diagnosis (Observational studies, all ages)

Screening with mammography* compared to no screening

Outcomes	Absolute effects		Relative effect (95% CI)	№ of participants (studies)	Quality of the evidence (GRADE)	Comments
	Risk with Usual Care (Assumed Risk)	Absolute effect (95% CI)				
Distant degree of spread at diagnosis	NR	Not estimable**	RR 0.44 (0.37 to 0.52)	869,857 (1 study ¹)	⊕○○○ VERY LOW a,b,c,d,e	We are very uncertain about if screening with mammography compared to no screening reduces the proportion of individuals with distant degree of breast cancer spread at diagnosis
Stage II+ at diagnosis	1.81 per 1000	0.51 fewer per 1000 (0.43 fewer to 0.58 fewer)	Incidence Rate ratio 0.72 (0.68 to 0.76)	413,447 (1 study ²)	⊕○○○ VERY LOW f,g, b,c,e	Using a threshold of 3 fewer breast cancers being diagnosed at stage II or higher per 1,000, we are very uncertain whether screening makes little to no difference in the number of individuals with stage II+ at diagnosis in those at general population risk for breast cancer.

*The corresponding risk (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

**Study did not provide baseline risk values for usual care or breast cancer screening groups to calculate absolute risk.

CI: Confidence interval; RR: Risk ratio

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

a. Downrated twice for risk of bias. Study at high risk of bias (RoB score for JBI cohort tool=4/11). Non-screening population inferred from census-derived population data rather than individual data and lack of reporting on outcome measurement. Lack of adjustment for important confounding factors (use of HRT, breast density). Unclear report of average follow-up time for population and no description of number of women lost to follow-up.

b. Not downrated for inconsistency. Single study evaluated outcome (unable to evaluate heterogeneity).

c. Not downrated for indirectness. Studies used population-based approach which was reflective of general population

d. Not downrated for imprecision. Unable to calculate absolute effects to determine if benefit for threshold is crossed, so a minimally contextualized approach was used. The total population is large (>2000) and there is a large event rate (>300). Given the large sample sizes and that the confidence interval does not include the null value, an optimal sample size calculation is not warranted.

e. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

f. Downrated once for risk of bias. Study at moderate risk of bias (RoB score for JBI cohort tool=7/11). Lack of adjustment for important confounding factors (use of HRT, breast density). No description of number of women lost to follow-up.

g. Not downrated for imprecision. Large population and CI does not cross threshold for breast cancer screening benefit for stage III at diagnosis.

Bibliography:

A: de Glas 2014³⁸

B: Helvie 2014³⁹

C: Wilkinson 2022⁴⁰

Explanations

1. Unadjusted incidence rate ratio (IRR)
2. Comparison of screening period to pre-screening period of 1995-1997.
3. Study at Low risk of bias (RoB score for JBI Quasi-experimental tool=7/9). No information on loss-to follow-up patients and reliability of outcome measures.
4. Study at moderate risk of bias (RoB score for JBI Quasi-experimental tool=6/9). No information on control group, loss-to follow-up patients and reliability of outcome measures
5. Study at low risk of bias (RoB score for JBI Quasi-experimental tool=8/9). Noted that there may be differences in access to care across screening and non-screening jurisdictions beyond screening that could impact the stage of BC diagnosis.
6. Unable to evaluate imprecision using thresholds, as the baseline rates were not available to allow the calculation of absolute effects. Therefore, a minimally contextualized approach was used. The total population is large (>2000) and there is a large event rate (>300). We did not downrate for imprecision.
7. Not downrated for inconsistency. Single study evaluated outcome (unable to evaluate heterogeneity).
8. Downrated once for indirectness. Pre-screening periods ranged across studies between 1958 and 2004. There are population-level differences that may affect mortality beyond the introduction of mammography screening between the pre-screening period and the post-screening period.
9. Downrated once for indirectness. Study assessed the effect of screening programs on outcomes of interest, rather than the effect of individual-level mammography screening. Not all women in screening jurisdictions participated in screening and it is unknown if BCs were diagnosed by screening or through other means (e.g., interval cancers, symptoms).

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

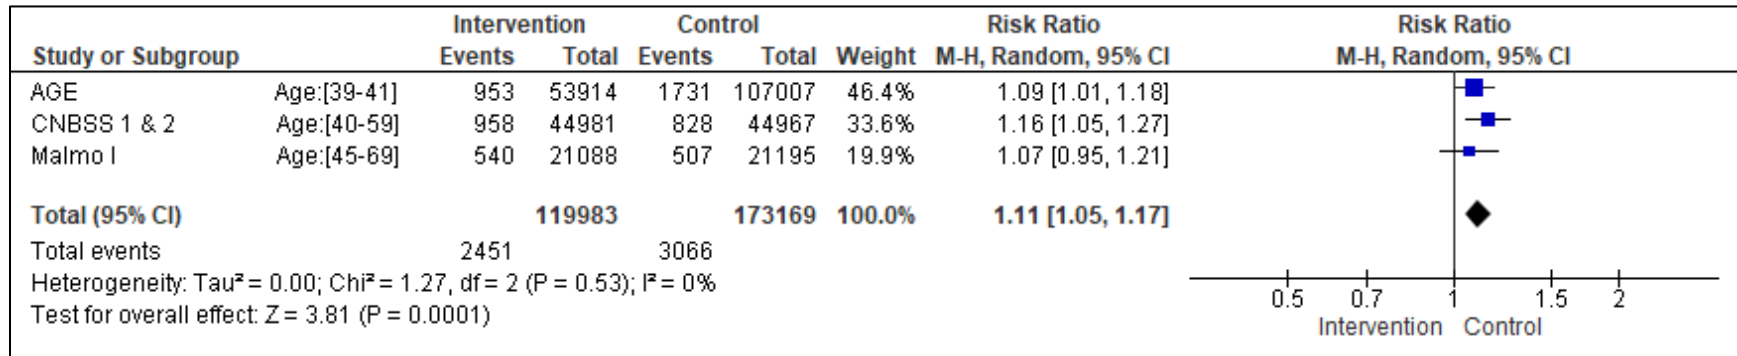

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

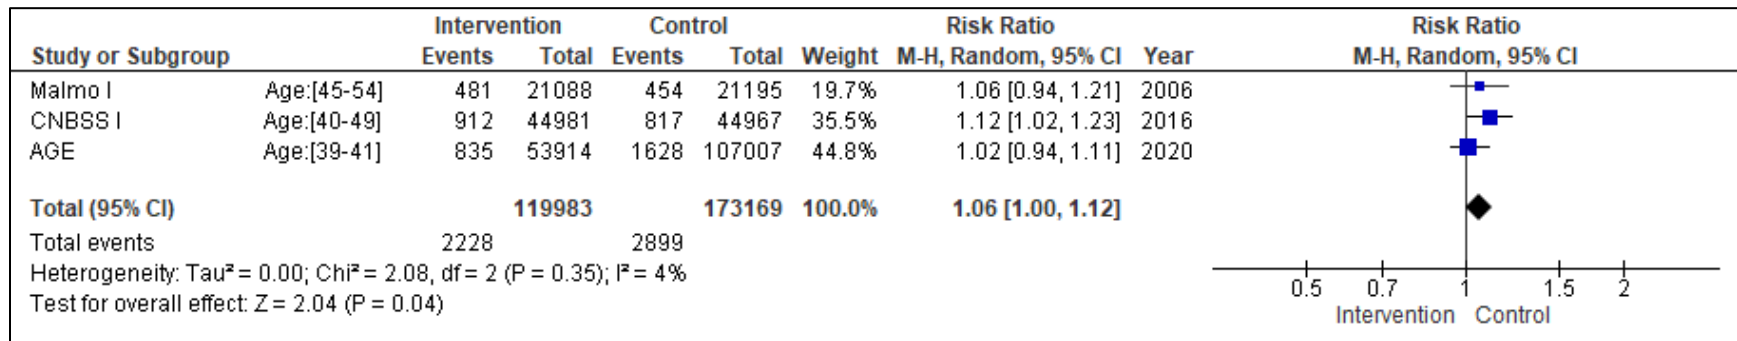

- a. We downrated once for risk of bias. Randomisation and allocation concealment were either not reported or there were serious deficiencies in these areas.
- b. Approximately half point estimates in our pooled estimate cross our threshold, we downrated once for inconsistency.
- c. Downrated once for indirectness. Data are from trials initiated in the 1960s-1990s and some trial estimates included participants outside the previously defined age decades (e.g., in the 40-49 age decade, one study included some individuals in their 50s).
- d. Not rated down for imprecision. Clinical decision threshold set at 5.
- e. Not downrated for publication bias. Cannot assess publication bias (insufficient number of trials).
- f. Not downrated for inconsistency; all point estimates in our pooled analysis lie to one side of our threshold.

Age 50-59 (invasive only)

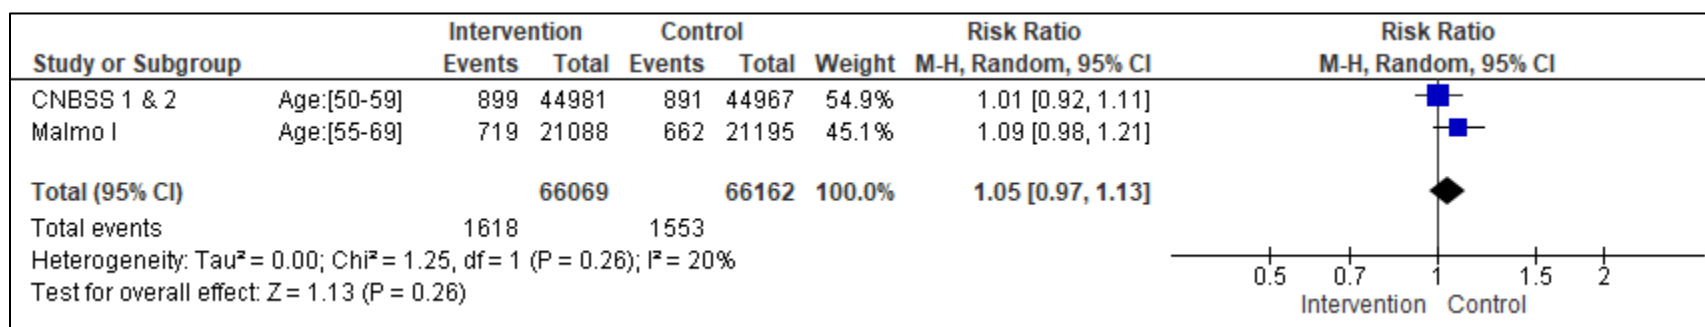

Table 12: Overdiagnosis (Observational studies, stratified by age)

Mammography +/- CBE compared to Usual Care

Outcomes	Summary†	No of participants (studies)	Quality of the evidence (GRADE)	Comments
Overdiagnosis invasive + in situ cancers (40-49 years) Range of follow-up (yrs): 8 years Screening interval: biennial	One study reported the number of invasive and in situ breast cancers among women 49 to 52 years and found a rate of 3.87 per 1,000 person years in the screened group and 2.45 per 1,000 person years in the unscreened group [RR 1.49 (95% CI 1.18 to 1.88)].	Unclear (1 study) ¹	⊕○○○ VERY LOW ^{a-e}	We are very uncertain whether screening leads to at least 5 overdiagnosed cancers in individuals aged 40 to 49 years.
Overdiagnosis invasive + in situ cancers (50-59 years) Range of follow-up (yrs): 8 to 13 years Screening interval: biennial	Two studies reported the number of invasive and in situ breast cancers. One study reported among 53- to 59-year-olds and found a rate of 2.77 per 1,000 person years in the screened group and 3.19 per 1,000 person years in the unscreened group. The second study found a rate of 3.74 per 1,000 individuals in the screening group and 3.40 per 1,000 individuals in the control group among 50- to 69-year-olds.	Unclear (2 studies) ^{1,2}	⊕○○○ VERY LOW ^{a,d-g}	We are very uncertain whether screening leads to at least 5 overdiagnosed cancers in individuals aged 50 to 59 years.
Overdiagnosis invasive + in situ cancers (60-69 years) Range of follow-up (yrs): 8 to 13 years Screening interval: biennial	Two studies reported the number of invasive and in situ breast cancers. One study reported among 60- to 69-year-olds and found a rate of 3.59 per 1,000 person years in the screened group and 3.44 per 1,000 person years in the unscreened group. The second study found a rate of 3.74 per 1,000 individuals in the screening group and 3.40 per 1,000 individuals in the control group among 50- to 69-year-olds.	Unclear (2 studies) ^{1,2}	⊕○○○ VERY LOW ^{a,d-g}	We are very uncertain whether screening leads to at least 5 overdiagnosed cancers in individuals aged 60 to 69 years.
Overdiagnosis invasive + in situ cancers (70-74 years) Range of follow-up (yrs): 15 years Screening interval: 3 years	One study reported the number of invasive and in situ breast cancers among women 70 to 74 years and found a rate of 61 per 1,000 individuals in the screened group and 41 per 1,000 individuals in the unscreened group [HR 1.47 (95% CI 1.19 to 1.81)].	19,925 (1 study) ³	⊕⊕○○ LOW ^{b,d,e,h,i}	Screening may lead to at least 5 overdiagnosed cancers in 1,000 individuals aged 70 to 74 years.
Overdiagnosis invasive + in situ cancers (75 years and older) Range of follow-up (yrs): 15 years Screening interval: 3 years	One study reported the number of invasive and in situ breast cancers among women 75 to 84 years and found a rate of 49 per 1,000 individuals in the screened group and 26 per 1,000 individuals in the unscreened group (HR 1.92 (95% CI 1.60 to 2.30)). The same study reported for those aged 85 years or older and found a rate of 28 per 1,000 individuals in the screened group and 13 per 1,000 individuals in the unscreened group [HR 2.20 (95% CI 1.43 to 3.40)].	34,710 (1 study) ³	⊕⊕○○ LOW ^{b,d,e,h,i}	Screening may lead to at least 5 overdiagnosed cancers in 1,000 individuals aged 75 years or older.

CI: Confidence interval, RR: relative risk, HR: hazard ratio

Bibliography: 1 Lund 2018⁴⁴; 2: Puliti 2017³⁷; 3: Richman 2023⁴⁵

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

- a. Downrated once for risk of bias. One study had a follow up time deemed not sufficient to be long enough for outcomes to occur (at least 10-15 years) and there are concerns with adjusting for lead time or self selection bias.
- b. Not downrated for inconsistency. One study assessed.
- c. Downrated once for indirectness. We reported what study authors report and some study subjects in their 50s were included in the estimate, it's not truly a reflection of the desired age group.
- d. Not downrated for imprecision. Narrative analysis. Clinical decision threshold of 5 more or fewer. Unable to assess OIS.
- e. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.
- f. Downrated once for inconsistency. Reporting of estimates varied between studies. One cannot be confident that the same methodological approach was used.
- g. Downrated once for indirectness. We reported what study authors report and some study subjects in their 50s or 60s were missing in the estimate, it's not truly a reflection of the desired age group.
- h. Not downrated for risk of bias.
- i. Not downrated for indirectness.

Explanations

- Downrated once for risk of bias due to a lack of reporting for how interval cancers were detected and unclear reporting on who was used in the analysis.
- Not downrated for inconsistency. Single study evaluated for outcome.
- Downrated once for indirectness. Data are from trials initiated in the 1960s-1990s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect may differ if applied to today's Canadian screening context. There are no high-quality clinical trials examining the impact of screening on interval cancers using contemporary screening methods.
- The 95% CI does not cross the clinical decision threshold; therefore, we did not rate down for imprecision.
- Downrated once for risk of bias. Studies ranged from moderate to high risk of bias. Lack of reporting for how interval cancers were detected and unclear reporting on who was used in the analysis.
- Inconsistency is moderately high ($I^2 = 61\%$). Rated down once.
- Inconsistency is moderately high ($I^2 = 52\%$). Rated down once.
- Inconsistency is moderately high ($I^2 = 57\%$). Rated down once.
- Downrated once for risk of bias. Lack of reporting for how interval cancers were detected and missing important demographic details in intervention group.
- According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

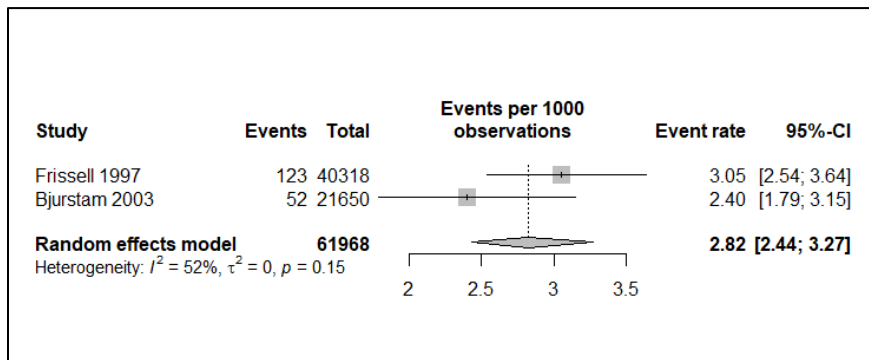

Table 13 forest plots

Forest plot for Invasive and DCIS (All ages):

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

- a. Downrated once for risk of bias. Randomisation and allocation concealment were either not reported (Malmö I, Swedish two county [Kopparberg]) or there were serious deficiencies in these areas (CNBSS 1&2, Stockholm).
- b. All point estimates in our pooled analysis lie to one side of our threshold. We did not rate down for inconsistency.
- c. Downrated once for indirectness. Data are from trials initiated in the 1960s-1990s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect may differ if applied to today's Canadian screening context. There are no high-quality clinical trials examining the impact of screening on breast cancer treatment-related morbidity using contemporary screening methods. For some studies, the control group received screening after the screening period (Stockholm and Swedish Two County [Kopparberg]).
- d. Downrated once for imprecision. CI crosses threshold for breast cancer screening harm for breast cancers requiring a full mastectomy (versus lumpectomy).
- e. Downrated once for risk of bias. Randomisation and allocation concealment were not reported (Malmö I, Swedish two county [Kopparberg]).
- f. Downrated once for indirectness. Trial data is from trials mainly initiated in the 1970s-1980s and the intervention groups were primarily screened with film mammography. Due to advances in mammography technology and treatment practices, we expect that the magnitude of screening effect would differ if applied to today's Canadian screening context. In one of the studies, the control group received screening after the screening period (Swedish Two County [Kopparberg]).
- g. Not downrated for imprecision. The CI does not cross the threshold for breast cancer screening harm for breast cancers requiring radiotherapy.
- h. Not downrated for imprecision. The CI does not cross the threshold for breast cancer screening benefit or harm for breast cancers requiring chemotherapy.
- i. According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

Table 15: Treatment-related morbidity (Observational studies, all ages, adherence to screen analysis)

Screening with mammography* compared to no screening

Outcomes	Absolute effects		Relative effect (95% CI)	№ of participants (studies)	Quality of the evidence (GRADE)	Comments
	Risk with Usual Care (Assumed Risk)	Absolute effect (95% CI)				
Breast cancers with conservative surgery as treatment Range of follow-up (yrs): Median 11, IQR 9-13	1.83/1000	0.9 more per 1,000 (from 0.7 more to 1.1 more)	Rate ratio 1.5 (1.4 to 1.6)	413,447 (1 study ¹)	⊕○○○ VERY LOW a,b,c,d,e	Using a threshold of 2 fewer breast cancers requiring a full mastectomy per 1,000, screening may make little to no difference in the number of breast cancers with conservative surgery as treatment in individuals in a general population.
Breast cancers with mastectomy as treatment Range of follow-up (yrs): Median 11, IQR 9-13	1.24/1000	0.4 fewer per 1,000 (from 0.35 fewer to 0.46 fewer)	Rate ratio 0.68 (0.63 to 0.72)	413,447 (1 study ¹)	⊕○○○ VERY LOW a,b,c,d,e	Using a threshold of 2 fewer breast cancers requiring a full mastectomy per 1,000, screening may make little to no difference in the number of breast cancers with mastectomy as treatment in individuals in a general population.

*The corresponding risk (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).
CI: Confidence interval; RR: Risk ratio

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

- a. Study downrated once for moderate risk of bias (RoB score for JBI cohort tool=7/11). Lack of adjustment for important confounding factors (use of HRT, breast density). No description of number of women lost to follow-up.
- b. Not downrated for inconsistency. Single study evaluated outcome (unable to evaluate heterogeneity).
- c. Not downrated for indirectness. Studies used population-based approach which was reflective of general population.
- d. Not downrated for imprecision. Large population and CI does not cross threshold for breast cancer screening benefit for breast cancers requiring a full mastectomy (2 less breast cancers requiring mastectomy).
- e. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

Table 16: Treatment-related morbidity (Observational studies, by age subgroup, stop screening analysis)

“Continue Screening” After Baseline Examination compared to “Stop Screening” After Baseline Examination					
Outcomes	70-74 Age Subgroup	75-84 Age Subgroup	No of participants (studies)	Quality of the evidence (GRADE)	Comments
Simple mastectomy # of follow-up (yrs): 8.0	The proportion of women (aged 70-74) diagnosed with breast cancer who received simple mastectomy in the continue screening strategy was 11.3 (10.8–11.8) and 10.4 (9.5–11.3) in the stop screening strategy group (absolute difference 9 more per 1,000).	The proportion of women (aged 75-84) diagnosed with breast cancer who received simple mastectomy in the continue screening strategy was 10.8 (10.3–11.2) and 10.1 (9.4–10.9) in the stop screening strategy group (absolute difference 7 more per 1,000)	2,639,194 (1 study) ¹	 LOW _{a,b,c,d,e}	We found low certainty evidence comparing the proportions of women requiring simple mastectomy among those who continued mammography screening and those who stopped screening in their 70s (70-74 and 75-84 age groups).
Radical mastectomy # of follow-up (yrs): 8.0	The proportion of women (aged 70-74) diagnosed with breast cancer who received radical mastectomy in the continue screening strategy was 13.9 (13.4–14.5) and 18.2 (17.0–19.4) in the stop screening strategy group (absolute difference 43 fewer per 1,000)	The proportion of women (aged 75-84) diagnosed with breast cancer who received radical mastectomy in the continue screening strategy was 14.2 (13.7–14.6) and 17.0 (16.0–17.9) in the stop screening strategy group (absolute difference 28 fewer per 1,000).	2,639,194 (1 study) ¹	 LOW _{a,b,c,d,e}	We found low certainty evidence comparing the proportions of women requiring radical mastectomy among those who continued mammography screening and those who stopped screening in their 70s (70-74 and 75-84 age groups).
Radiotherapy # of follow-up (yrs): 8.0	The proportion of women (aged 70-74) diagnosed with breast cancer who received radiotherapy in the continue screening strategy was 51.0 (50.3–51.8) and 39.9 (38.6–41.3) in the stop screening strategy group (absolute difference 111 more per 1,000)	The proportion of women (aged 75-84) diagnosed with breast cancer who received radiotherapy in the continue screening strategy was 41.2 (40.4–41.9) and 31.9 (30.7–33.1) in the stop screening strategy group (absolute difference 93 more per 1,000).	2,639,194 (1 study) ¹	 LOW _{a,b,c,d,e}	We found low certainty evidence comparing the proportions of women requiring radiotherapy among those who continued mammography screening and those who stopped screening in their 70s (70-74 and 75-84 age groups).
Chemotherapy # of follow-up (yrs): 8.0	The proportion of women (aged 70-74) diagnosed with breast cancer who received chemotherapy in the continue screening strategy was 15.2 (14.7–15.8) and 21.1 (20.0–22.1) in the stop screening strategy group (absolute difference 59 fewer per 1,000)	The proportion of women (aged 75-84) diagnosed with breast cancer who received chemotherapy in the continue screening strategy was 8.6 (8.3–9.1) and 11.5 (10.6–12.3) in the stop screening strategy group (absolute difference 29 fewer per 1,000).	2,639,194 (1 study) ¹	 LOW _{a,b,c,d,e}	We found low certainty evidence comparing the proportions of women requiring chemotherapy among those who continued mammography screening and those who stopped screening in their 70s (70-74 and 75-84 age groups).

1: Garcia-Albeniz 2020¹⁹

- a. We did not downgrade for risk of bias. Study was judged to be of moderate quality using the JBI critical appraisal tool for cohort studies.
- b. We did not downgrade for inconsistency (only one study included).
- c. We did not downgrade for indirectness. The study answers the question of stopping versus continuing screening and all patients have received at least one baseline mammography.
- d. Unable to evaluate imprecision using thresholds, as the baseline rate of treatment is not provided in the “stop screening” group to allow the calculation of absolute effects. Therefore, a minimally contextualized approach was used. The total population is large (>2000) and there is a large event rate (>300). We did not downgrade for imprecision.
- e. According to Egger et al.¹¹, 10 studies are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

Table 17: Additional imaging (no cancer)

Table 17a: Additional imaging with or without biopsy (no cancer) – by age subgroup

Outcomes	Calculated Estimate (2011-2012 CPAC Data)**	Calculated Estimate (2019 British Columbia Data)**	Quality of the evidence (Based on GRADE*)	Comments
Additional imaging with or without biopsy (no cancer) over 10 years (40-49 years)†	367.5 per 1000	477.6 per 1000	⊕⊕⊕○ MODERATE a,b,c,d,e	Screening probably leads to at least 150 women requiring additional imaging with or without biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (40-49 years)
Additional imaging with or without biopsy (no cancer) over 10 years (50-59 years)†	365.5 per 1000	410.5 per 1000	⊕⊕⊕○ MODERATE a,b,c,d,e	Screening probably leads to at least 150 women requiring additional imaging with or without biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening at age 50)
Additional imaging with or without biopsy (no cancer) over 10 years (50-59 years)‡	286.4 per 1000	285.2 per 1000	⊕⊕⊕○ MODERATE a,b,c,d,e	Screening probably leads to at least 150 women requiring additional imaging with or without biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening prior to age 50)
Additional imaging with or without biopsy (no cancer) over 10 years (60-69 years)‡	257.2 per 1000	252.4 per 1000	⊕⊕⊕○ MODERATE a,b,c,d,e	Screening probably leads to at least 150 women requiring additional imaging with or without biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (60-69 years)
Additional imaging with or without biopsy (no cancer) over 10 years (70+ years)‡	220.4 per 1000	238.4 per 1000	⊕⊕⊕○ MODERATE a,b,c,d,e	Screening probably leads to at least 150 women requiring additional imaging with or without biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (70+ years)

*GRADE ratings are not typically applied to the context of primary evidence sets generated by analyses of quality indicator surveillance data. However, our judgements of the overall certainty of evidence have been informed by similar considerations used in the GRADE process for effectiveness data.

†Scenario 1: Assuming started biennial screening in current age decade (calculated using one initial screen and three subsequent screens over a 10-year period).

‡Scenario 2: Assuming started biennial screening in prior age decade (calculated using four subsequent screens over a 10-year period).

**Data Sources: Using data from 2011- 2012 from the 2016 CPAC report⁴⁸, we estimated the approximate rate of additional imaging with or without biopsy (no cancer) for women in each age decade over a 10 year-period (Table 7A). The BC estimates were estimated using breast screening program outcome indicators by 10-year age groups for 2019 for the “overall” risk groups (Table 9). See supplemental KQ1 GRADE Material, Appendix 6, part E for an example calculation.

Additional imaging estimates per screening cycle were calculating by subtracting cancer detection rates (invasive + DCIS) from abnormal call rates, stratified by age decade and if data were related to an “initial” or “subsequent” screen. We assumed women received four screens over a 10-year period, if the majority of women would receive a screen every 2-3 years (approximating biennial screening for the majority noting that some provinces currently offer⁴⁹ or recommend⁵⁰ annual screening in women aged 40-49 or starting at age 45). Scenario 1 assumes women start screening in that age decade and receive four screens over 10 years (one initial and three subsequent) (age groups: 40-49 and 50-59†). Scenario 2 assumed women started screening in prior age decades and therefore received four subsequent screens over a 10-year period (age groups: 50-59‡, 60-69, 70+).

- a. The CPAC quality indicator data was used from the Canadian Breast Cancer Screening Database (CBCSD), which contained relatively complete data from participating provinces and territories for the quality indicators of interest in 2011-2012. The BC estimates were estimated using breast screening program outcome indicators by 10-year age groups for 2019, which should contain complete data. We did not downrate for risk of bias.
- b. Estimates were calculated using quality indicators from screen-level data. Thus, we have no measure of imprecision in the data. All point estimates cross the minimum threshold for important effect (150 women with no cancer who require either imaging alone or imaging plus biopsy per 1000 screens).
- c. We did not downrate for inconsistency. All age estimates for both the CPAC and the BC data fall above our threshold of 150 patients requiring additional imaging with or without biopsy (no cancer) per 1000 screens.
- d. There appears to be an increase in recall rates over time (see Supplemental KQ1 GRADE Material, Appendix 6) depending on the data source. However, our conclusions about the rates of additional imaging with or without biopsy (no cancer) are unlikely to change, as the rates remain relatively consistent using more recent CPAC data and provincial data and above our clinical decision threshold. We did not downrate for indirectness.
- e. We uprated our overall conclusion to moderate certainty of evidence as imaging recall estimates are similar across different data sources and consistently cross our threshold for clinical decision making.

Table 17b: – Additional imaging no biopsy (no cancer) – by age subgroup

Outcomes	Calculated Estimate (2011-2012 CPAC Data)**	Quality of the evidence (Based on GRADE*)	Comments
Additional imaging no biopsy (no cancer) over 10 years (40-49 years)†	312.8 per 1000	⊕⊕⊕○ MODERATE a,b,c,d	Screening probably leads to at least 150 women requiring additional imaging no biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (40-49 years)
Additional imaging no biopsy (no cancer) over 10 years (50-59 years)†	319.3 per 1000	⊕⊕⊕○ MODERATE a,b,c,d	Screening probably leads to at least 150 women requiring additional imaging no biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening at age 50)
Additional imaging no biopsy (no cancer) over 10 years (50-59 years)‡	252.4 per 1000	⊕⊕⊕○ MODERATE a,b,c,d	Screening probably leads to at least 150 women requiring additional imaging no biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening prior to age 50)
Additional imaging no biopsy (no cancer) over 10 years (60-69 years)‡	224.4 per 1000	⊕⊕⊕○ MODERATE a,b,c,d	Screening probably leads to at least 150 women requiring additional imaging no biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (60-69 years)
Additional imaging no biopsy (no cancer) over 10 years (70+ years)‡	190 per 1000	⊕⊕⊕○ MODERATE a,b,c,d	Screening probably leads to at least 150 women requiring additional imaging no biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (70+ years)

*GRADE ratings are not typically applied to the context of primary evidence sets generated by analyses of quality indicator surveillance data. However, our judgements of the overall certainty of evidence have been informed by similar considerations used in the GRADE process for effectiveness data.

†Scenario 1: Assuming started biennial screening in current age decade (calculated using one initial screen and three subsequent screens over a 10-year period).

‡Scenario 2: Assuming started biennial screening in prior age decade (calculated using four subsequent screens over a 10-year period).

**Data Sources: Using data from 2011- 2012 from the 2016 CPAC report⁴⁸, we estimated the approximate rate of additional imaging with or without biopsy (no cancer) for women in each age decade over a 10 year-period (Table 7A).

Additional imaging estimates per screening cycle were calculating by subtracting cancer detection rates (invasive + DCIS) and the additional imaging and biopsy (no cancer) from the abnormal call rates, stratified by age decade and if data were related to an “initial” or “subsequent” screen. See supplemental KQ1 GRADE Material, Appendix 6, part E for an example calculation.

We assumed women received four screens over a 10-year period, if the majority of women would receive a screen every 2-3 years (approximating biennial screening for the majority, noting that some provinces currently offer⁴⁹ or recommend⁵⁰ annual screening in women aged 40-49 or starting at age 45. Scenario 1 assumes women start screening in that age decade and receive four screens over 10 years (one initial and three subsequent) (age groups: 40-49 and 50-59†). Scenario 2 assumed women started screening in prior age decades and therefore received four subsequent screens over a 10-year period (age groups: 50-59‡, 60-69, 70+).

- The CPAC quality indicator data was used from the Canadian Breast Cancer Screening Database (CBCSD), which contained relatively complete data from participating provinces and territories for the quality indicators of interest in 2011-2012.
- Estimates were calculated using quality indicators from screen-level data. Thus, we have no measure of imprecision in the data. All point estimates cross the minimum threshold for important effect (threshold used was 150 women who do not have cancer and require additional imaging and no biopsy per 1000 screens).
- There appears to be an increase in recall rates over time (see Supplemental KQ1 GRADE Material, Appendix 6) depending on the data source. However, our conclusions about the rates of additional imaging no biopsy (no cancer) are unlikely to change, as the rates remain relatively consistent using more recent CPAC data and provincial data and above our clinical decision threshold. We did not downgrade for indirectness.
- We updated our overall conclusion to moderate certainty of evidence as imaging recall estimates are similar across different data sources and consistently cross our threshold for clinical decision making.

Table 17c: – Additional imaging and biopsy (no cancer) – by age subgroup

Outcomes	Calculated Estimate (2011-2012 CPAC Data)	Quality of the evidence (Based on GRADE*)	Comments
Additional imaging and biopsy (no cancer) over 10 years (40-49 years)†	54.7 per 1000	⊕⊕⊕○ MODERATE _{a,b,c,d}	Screening probably leads to at least 15 women requiring additional imaging and biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (40-49 years)
Additional imaging and biopsy (no cancer) over 10 years (50-59 years)†	46.2 per 1000	⊕⊕⊕○ MODERATE _{a,b,c,d}	Screening probably leads to at least 15 women requiring additional imaging and biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening at age 50)
Additional imaging and biopsy (no cancer) over 10 years (50-59 years)‡	34.0 per 1000	⊕⊕⊕○ MODERATE _{a,b,c,d}	Screening probably leads to at least 15 women requiring additional imaging and biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (50-59 years, started screening prior to age 50)
Additional imaging and biopsy (no cancer) over 10 years (60-69 years)‡	32.8 per 1000	⊕⊕⊕○ MODERATE _{a,b,c,d}	Screening probably leads to at least 15 women requiring additional imaging and biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (60-69 years)
Additional imaging and biopsy (no cancer) over 10 years (70+ years)‡	30.4 per 1000	⊕⊕⊕○ MODERATE _{a,b,c,d}	Screening probably leads to at least 15 women requiring additional imaging and biopsy (no cancer) in 1000 women screened every 2-3 years over a 10-year period (70+ years)

*GRADE ratings are not typically applied to the context of primary evidence sets generated by analyses of quality indicator surveillance data. However, our judgements of the overall certainty of evidence have been informed by similar considerations used in the GRADE process for effectiveness data.

†Scenario 1: Assuming started biennial screening in current age decade (calculated using one initial screen and three subsequent screens over a 10-year period).

‡Scenario 2: Assuming started biennial screening in prior age decade (calculated using four subsequent screens over a 10-year period).

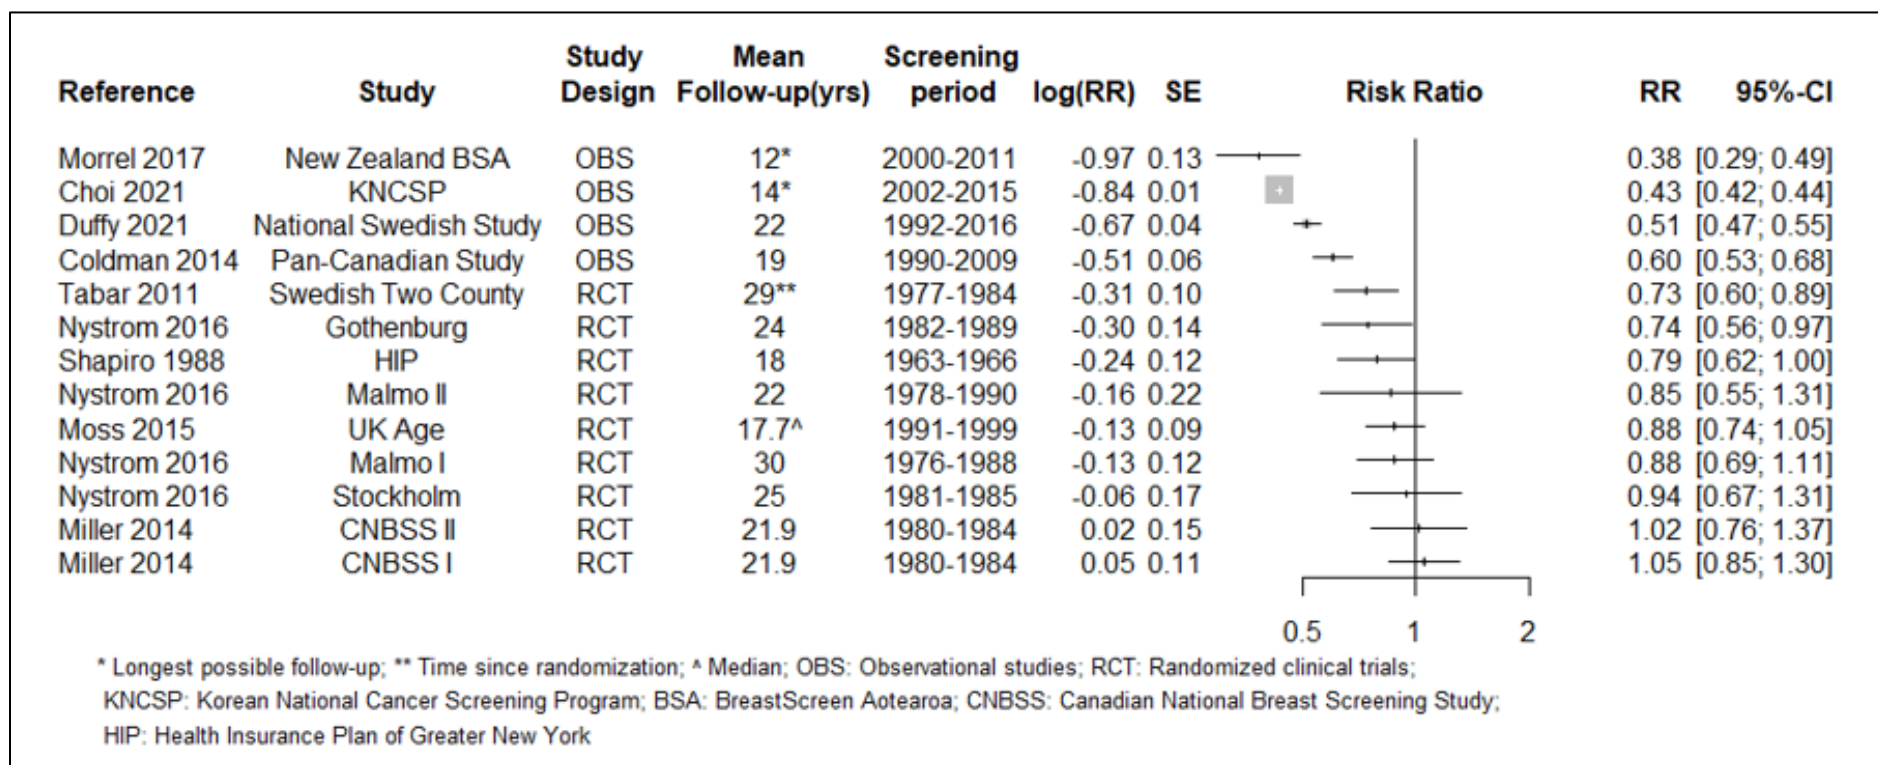

**Data Sources: Using data from 2011- 2012 from the 2016 CPAC report⁴⁸, we estimated the approximate rate of additional imaging with or without biopsy (no cancer) for women in each age decade over a 10 year-period (Table 7A).

Additional imaging estimates per screening cycle were based on reported non-malignant biopsy rates, stratified by age decade and if data were related to an “initial” or “subsequent” screen. See supplemental KQ1 GRADE Material, Appendix 6, part E for an example calculation.

We assumed women received four screens over a 10-year period, if the majority of women would receive a screen every 2-3 years (approximating biennial screening for the majority, noting that some provinces currently offer⁴⁹ or recommend⁵⁰ annual screening in women aged 40-49 or starting at age 45. Scenario 1 assumes women start screening in that age decade and receive four screens over 10 years (one initial and three subsequent) (age groups: 40-49 and 50-59†). Scenario 2 assumed women started screening in prior age decades and therefore received four subsequent screens over a 10-year period (age groups: 50-59‡, 60-69, 70+)

- The CPAC quality indicator data was used from the Canadian Breast Cancer Screening Database (CBCSD), which contained relatively complete data from participating provinces and territories for the quality indicators of interest in 2011-2012. The BC estimates were estimated using breast screening program outcome indicators by 10-year age groups for 2019, which should contain complete data. We did not downrate for risk of bias.
- Estimates were calculated using quality indicators from screen-level data. Thus, we have no measure of imprecision in the data. All point estimates cross the minimum threshold for important effect (15 women requiring additional imaging and biopsy per 1000 screens).
- The rates of additional imaging and biopsies (no cancer) appear to have remained consistent over time based on provincial data sources (Appendix 6, part B). We did not downrate for indirectness.
- We uprated our overall conclusion to moderate certainty of evidence as imaging recall estimates are similar across different data sources and consistently cross our threshold for clinical decision making.

Appendix 9 – Cohort and RCT forest plot

Appendix 10 - Final Working Group Thresholds for GRADE

Outcome	Threshold
Breast Cancer Mortality	Threshold One: For every 1,000 patients that undergo screening, there will be 1 less death due to breast cancer Threshold Two: For every 1,000 patients that undergo screening, there will be 0.5 less deaths due to breast cancer
All-Cause Mortality	For every 1,000 patients that undergo screening, there will be 1 less death due to any cause
Breast Cancers Requiring Chemotherapy	For every 1,000 patients that undergo screening, there will be 2 less breast cancers requiring chemotherapy
Breast Cancers Requiring a Full Mastectomy (Versus Lumpectomy)	For every 1,000 patients that undergo screening, there will be 2 less breast cancers requiring mastectomy
Breast Cancers Requiring Axial Lymph Node Dissection	For every 1,000 patients that undergo screening, there will be 2 less breast cancers requiring axial lymph node dissection
Breast Cancers Requiring Radiotherapy	For every 1,000 patients that undergo screening, there will be 5 less breast cancers requiring radiotherapy
Breast Cancers Being Diagnosed at Stage III or Higher	For every 1,000 patients that undergo screening, there will be 2 less breast cancers diagnosed at stage III or higher
Breast Cancers Being Diagnosed at Stage II or Higher	For every 1,000 patients that undergo screening, there will be 3 less breast cancers diagnosed at stage II or higher
Metastatic cancer (stage IV)	For every 1,000 patients that undergo screening, there will be 1 less metastatic breast cancer diagnosed.
Overdiagnosed Cancers	For every 1,000 patients that undergo screening, there will be 5 more overdiagnosed breast cancers
Additional imaging +/- biopsy	For every 1,000 patients that undergo screening, 150 will experience one or more additional imaging +/- biopsy.
Additional imaging with biopsy	For every 1,000 patients that undergo screening, 15 will experience one or more additional imaging with biopsy.
Interval cancers	For every 1,000 patients that undergo screening, 6 will have an interval cancer.

Appendix 11 - Working group survey for patient values and preferences towards screening for breast cancer

Purpose: To consider the working group’s perspective on what effect (or risk reduction) patients would consider an important or trivial effect of a breast cancer screening program. An example of this effect could be: 1 less death per 1,000 patients screened. We want to know if you think this effect is important or trivial.

Survey: We will present a series of questions based on certain effects (i.e., different risk reduction scenarios for each outcome). We want to determine one threshold (e.g., 50 less per 1,000 patients) for each outcome that the working group agrees would be important to the majority of patients during decision-making (or a minimally important effect). At this point, the question is abstract because only one outcome is considered at a time (all the other benefits, harms, or burdens of interventions and their magnitude are not considered). These judgments are challenging. If possible, reflect on the question based on your knowledge of primary studies, previous focus groups, conversations with friends or family, or shared decision-making with patients.

A few items to note:

- All effects are measured per 1,000 patients screened. If the risk reduction is <1 person (e.g., 0.4 less deaths per 1,000) you can think about it as per 10,000 patients screened (e.g., 4 less deaths per 10,000).
- Some scenarios involve a decrease (e.g., 1 less death per 1,000), while others involve an increase (e.g., 100 more false positives per 1,000) or simply state an associated rate (e.g., 2 interval cancers per 1,000).
- Please consider your answers in relation to a screening program consisting of 3 to 4 rounds of (annual or biannual) screening where patients are followed for 10 years after baseline.
- There’s no right or wrong answer. All thresholds can be trivial, all can be important, or it can vary.

1. Patients are considering the possibility of participating in a breast cancer screening program to reduce their risk of **dying from breast cancer**. Breast cancer screening lowers their risk in different scenarios in the table below over a period of 10 years. **Please choose an option that will reflect whether the majority of patients (>50%) would think this reduction in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 0.4 less deaths due to breast cancer over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 0.6 less deaths due to breast cancer over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, there will be 0.8 less deaths due to breast cancer over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 1 less death due to breast cancer over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 1.2 less deaths due to breast cancer over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 1.4 less deaths due to breast cancer over 10 years.	Choose an item.

If you would like to propose a different value in risk of dying from breast cancer, please note it here, otherwise please leave blank:

[Response]

2. Patients are considering the possibility of participating in a breast cancer screening program to reduce their risk of **dying from any cause**. Breast cancer screening lowers their risk in different scenarios in the table below over a period of 10 years. **Please choose an option that will reflect whether the majority of patients (>50%) would think this reduction in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 0.4 less deaths due to any cause over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 0.6 less deaths due to any cause over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, there will be 0.8 less deaths due to any cause over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 1 less death due to any cause over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 1.2 less deaths due to any cause over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 1.4 less deaths due to any cause over 10 years.	Choose an item.

If you would like to propose a different value in risk of dying from any cause, please note it here, otherwise please leave blank:

[Response]

3. Patients are considering the possibility of participating in a breast cancer screening program to reduce their risk of **breast cancers requiring chemotherapy (and associated complications)**. Breast cancer screening lowers their risk in different scenarios in the table below over a period of 10 years. **Please choose an option that will reflect whether the majority of patients (>50%) would think this reduction in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 1 less breast cancer requiring chemotherapy over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 2 less breast cancers requiring chemotherapy over 10 years.	Choose an item.

c.	For every 1,000 patients that participate in screening, there will be 3 less breast cancers requiring chemotherapy over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 4 less breast cancers requiring chemotherapy over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 5 less breast cancers requiring chemotherapy over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 6 less breast cancers requiring chemotherapy over 10 years.	Choose an item.

If you would like to propose a different value in risk of breast cancers requiring chemotherapy, please note it here, otherwise please leave blank:

[Response]

If you would like to propose a value in risk of breast cancers requiring a **full mastectomy (vs lumpectomy)**, please note it here, otherwise please leave blank:

[Response]

If you would like to propose a value in risk of breast cancers requiring **axial lymph node dissection (vs sentinel lymph node biopsy)**, please note it here, otherwise please leave blank:

[Response]

If you would like to propose a value in risk of breast cancers requiring **radiotherapy**, please note it here, otherwise please leave blank:

[Response]

4. Patients are considering the possibility of participating in a breast cancer screening program to reduce their risk of **being diagnosed with stage II or higher cancer**. Breast cancer screening lowers their risk in different scenarios in the table below over a period of 10 years. **Please choose an option that will reflect whether the majority of patients (>50%) would think this reduction in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 1 less \geq stage II cancer diagnosed over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 2 less \geq stage II cancer diagnosed over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, there will be 3 less \geq stage II cancer diagnosed over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 4 less \geq stage II cancer diagnosed over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 5 less \geq stage II cancer diagnosed over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 6 less \geq stage II cancer diagnosed over 10 years.	Choose an item.

If you would like to propose a different value in risk of being diagnosed with stage II or higher cancer, please note it here, otherwise please leave blank:

[Response]

5. Patients are considering the possibility of participating in a breast cancer screening program to reduce their risk of **being diagnosed with stage III or higher cancer**. Breast cancer screening lowers their risk in different scenarios in the table below over a period of 10 years. **Please choose an option that will reflect whether the majority of patients (>50%) would think this reduction in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 0.5 less \geq stage III cancer diagnosed over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 1 less \geq stage III cancer diagnosed over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, there will be 1.5 less \geq stage III cancer diagnosed over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 2 less \geq stage III cancer diagnosed over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 2.5 less \geq stage III cancer diagnosed over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 3 less \geq stage III cancer diagnosed over 10 years.	Choose an item.

If you would like to propose a different value in risk of being diagnosed with stage III or higher, please note it

[Response]

here, otherwise please leave blank:

6. Patients are considering the possibility of participating in a breast cancer screening program. Breast cancer screening may increase their risk of having an **overdiagnosed cancer** (i.e., a cancer that may never cause any harm or symptoms but leads to having a diagnosis (i.e., label) of cancer and may lead to unnecessary treatments or medications). **Please choose an option that will reflect whether the majority of patients (>50%) would think this increase in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, there will be 1 more overdiagnosed cancer over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, there will be 2 more overdiagnosed cancers over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, there will be 3 more overdiagnosed cancers over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, there will be 4 more overdiagnosed cancers over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, there will be 5 more overdiagnosed cancers over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, there will be 6 more overdiagnosed cancers over 10 years.	Choose an item.

If you would like to propose a different value in risk of having an overdiagnosed cancer, please note it here, otherwise please leave blank:

[Response]

7. Patients are considering the possibility of participating in a breast cancer screening program. Breast cancer screening may lead to at least one **false positive result which could require either imaging alone or imaging plus biopsy** (i.e., a false alarm). **Please choose an option that will reflect whether the majority of patients (>50%) would think this increase in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, 100 will experience one or more false positives over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, 125 will experience one or more false positives over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, 150 will experience one or more false positives over 10 years.	Choose an item.

d.	For every 1,000 patients that participate in screening, 175 will experience one or more false positives over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, 200 will experience one or more false positives over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, 225 will experience one or more false positives over 10 years.	Choose an item.

If you would like to propose a different value in having a **false positive result which could require either imaging alone or imaging plus biopsy**, please note it here, otherwise please leave blank:

[Response]

8. Patients are considering the possibility of participating in a breast cancer screening program. Breast cancer screening may lead to at least one **false positive result that requires biopsy and imaging** (i.e., a false alarm). **Please choose an option that will reflect whether the majority of patients (>50%) would think this increase in risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, 10 will experience one or more false positives over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, 12 will experience one or more false positives over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, 15 will experience one or more false positives over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, 18 will experience one or more false positives over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, 20 will experience one or more false positives over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, 25 will experience one or more false positives over 10 years.	Choose an item.

If you would like to propose a different value in risk of having a **false positive result that requires biopsy and imaging**, please note it here, otherwise please leave blank:

[Response]

9. Patients are considering the possibility of participating in a breast cancer screening program. Breast cancer screening may lead to **interval cancers** (i.e., breast cancer that was not recognized during the screening or that develops between regular screens). These interval cancers may be more likely to occur with certain screening strategies (e.g., annual vs biannual). **Please choose an option that will reflect whether the majority of patients (>50%) would think this associated risk is an important or trivial effect.**

	Risk reduction scenarios	Answer
a.	For every 1,000 patients that participate in screening, 2 will have an interval cancer over 10 years.	Choose an item.
b.	For every 1,000 patients that participate in screening, 6 will have an interval cancer over 10 years.	Choose an item.
c.	For every 1,000 patients that participate in screening, 8 will have an interval cancer over 10 years.	Choose an item.
d.	For every 1,000 patients that participate in screening, 10 will have an interval cancer over 10 years.	Choose an item.
e.	For every 1,000 patients that participate in screening, 12 will have an interval cancer over 10 years.	Choose an item.
f.	For every 1,000 patients that participate in screening, 15 will have an interval cancer over 10 years.	Choose an item.

If you would like to propose a different value in risk of having **an interval cancer**, please note it here, otherwise please leave blank:

[Response]

10. If you would like to leave any notes about any considerations you took when answering the survey or general comments, please note it here, otherwise please leave blank:

[Response]

Thank you!

Appendix 12 – Baseline and lifetime risk calculations

Table 1: Calculated general population baseline risk and moderately increased risk for breast cancer mortality

Age	Breast cancer mortality rate per 1,000 in screened group <i>Coldman</i>	SMR from screening <i>Coldman</i>	Breast cancer mortality rate per 1,000 in an unscreened group (General population risk)	Breast cancer mortality rate per 1,000 in an unscreened group (Moderately increased risk, family history)	Breast cancer mortality rate per 1,000 in an unscreened group (Moderately increased risk, dense breasts)
40-49	1.02	0.56	1.8	2.9	3.5
50-59	1.98	0.60	3.3	5.3	6.3
60-69	2.50	0.58	4.3	6.9	8.2
70-79	3.97	0.65	6.1	9.7	11.6

- Breast cancer mortality rate in a Canadian population was estimated from the Pan-Canadian study ([Coldman et al., 2014](#))
- One first degree relative increases the lifetime risk by 1.6 times ([Engmann et al., 2017](#))
 - E.g., For 40-49, the general population risk at 1.8 per 1,000 multiplied by 1.6 gives you 2.9 per 1,000 for family history.
- Dense breasts increases risk by 1.9 times ([Yueh-Hsia Chiu et al., 2010](#))
 - E.g., For 40-49, the general population risk at 1.8 per 1,000 multiplied by 1.9 gives you 3.5 per 1,000 for dense breasts.
- We assume the cancers diagnosed within the elevated risk population in unscreened women would have similar survival rates as those in the general risk population.

Table 2: Calculated baseline risk for all-cause mortality

Age	Number of deaths in Canadian females 2021	All-cause mortality rate per 1,000 over 10 years
40-49	3,144	12.7
50-59	7,889	30.6
60-69	17,643	71.3
70-74	13,603	140.6

- Baseline risk has been calculated using death and age-specific mortality rate data from [Statistics Canada](#) in 2021

Calculation to Estimate Potential Lifetime Breast Cancer Mortality Reduction for Screening Women in their 40s

The lifetime risk of a Canadian woman dying of breast cancer is about 27.8/1000⁵¹. 17.5% of those deaths arise from cancers diagnosed in women between ages 40 and 49⁵², so the risk of dying from those cancers is 4.86 / 1000. This rate is the result of some women who are unscreened and some who receive screening. Let p represent the fraction of women who are regularly screened.

An additional factor is that the cancer mortality statistics derive from a combination of women at general risk and those at increased risk. Let's assume that 95% are at general risk of dying from breast cancer if unscreened and 5% are at twice that risk. Further, we will make the somewhat arbitrary assumption that for these higher risk women screening with mammography does not reduce their risk of breast cancer death.

Let R_u represent the risk of dying of breast cancer if unscreened for those at general risk. From the Pan Canadian Study, the relative risk of dying of breast cancer for women who begin screening in their 40s is 0.56. We can then write for the overall mortality risk:

$$R_u [0.56 * p * .95] + R_u [(1-p) * .95] + 2 R_u * .05 = 4.86/1000$$

where the first term refers to the women at general risk who are screened, the second term to those at general risk who do not participate in screening and the third to those at elevated risk regardless of screening

$$\text{So that } R_u = 4.86/1000 / \{[0.56 * p * .95] + R_u [(1-p) * .95] + 2 R_u * .05\}$$

Then, if 60% of women historically participated in screening, $R_u = 6.1/1000$ and the absolute breast cancer mortality reduction for those who participate in screening is estimated as $0.44 * 6.1/1000 = \mathbf{2.68 \text{ per } 1000}$.

Appendix 13 – List of excluded studies

Appendix 14 – Study characteristics table

Study	Participants and Study Design	Intervention	Control	Outcomes
RCTs (n=3)				
Duffy 2020⁵³, United Kingdom and Duffy 2020⁴³, United Kingdom Trial/Screening Program: UK Age Trial - National Health Service Breast Screening Programme (NHSBSP)	Participants: Women aged 39–41 years were recruited from 23 screening units in England, Wales, and Scotland within the NHSBSP Study design: RCT Follow-up: <i>For Duffy 2020⁵³ and Duffy 2020⁴³:</i> Mean of 23 years; median of 22.8 years (IQR 21.8–24.0)	n=53,914 Type of mammography: NR Number of screening intervals: NR The intervention group was invited to an annual breast screen with film mammography, two view at first screen and single view thereafter, up to and including the calendar year of their 48th birthday. All screening in the trial was completed by 2006.	n=107,007 The control group received usual care during the intervention periods. At the age of 50 years, the control group became eligible for invitation to screening every 3 years as part of the NHSBSP and received their first invitation between age 50 and 52 years.	BC mortality, other/all-cause mortality, overdiagnosis
Tarone 1995³⁶, Canada Trial/Screening Program: CNBSS I – Additional analysis for Swedish Two County (Kopparberg & Ostergotland), Malmo I, HIP, Stockholm	Participants: Women aged 40-49 years were recruited from 15 urban centres in Canada with expertise in the diagnosis and treatment of Breast Cancer Study design: RCT Follow-up: Mean follow-up: 8.5 years	n=44,925 (CNBSS-I) Type of mammography: Two-view film screen mammography The screening group was invited to annual mammography and physical examination	n=44,910 (CNBSS-I) Participants in the control group received a single physical examination at enrollment into the study and usual medical care thereafter.	Stage at Diagnosis (stage II and higher, stage III and higher)
Observational studies (n=26)				
Choi 2021¹⁵, Korea Screening Program/Database: Korean National Cancer Screening Program (KNCSPP)	Participants: Women born between 1923-1963 (aged 40-79 years) who received an invitation to the KNCSPP for breast cancer screening between 2002 and 2003 Study design: Cohort Follow-up: Maximum 14 years for mortality outcomes (2002 to 2015); Mean 8.42 years screened and 7.52 years in non-screened	n=1,099,417 (screened at first invitation); n=5,026,186 (from non-screened to screened) Type of mammography: Women were invited for screen-film mammography, computed radiography, and full-field digital mammography Number of screening intervals: Over 70% of the screened women attended screening more than once during follow-up 2 rounds: 21.0%	n=2,047,569 (never screened); n=5,153,696 (from non-screened to screened) Women who never underwent BC screening during the follow-up period. Additionally, the control included the women-years of women who were eventually screened from the date of initial invitation (January 1, 2002; January 1, 2003) to the date of their first screening attendance	Breast cancer mortality, all-cause mortality, incidence of invasive BC

Study	Participants and Study Design	Intervention	Control	Outcomes
		3 rounds: 21.6% 4 rounds: 19.5% 5 rounds: 11.0% 6+ rounds: 3.0%		
Duffy 2021¹⁷, Sweden Screening Program/Database: Swedish Cause of Death Register of the Swedish National Board of Health and Welfare; Screening data: Sectra Medical Systems, Linköping	Participants: Swedish women eligible for screening mammography in nine counties from 1992 to 2016 (aged 40-69 years); 37078/549091 (~7%) participants previously had BC Study design: Cohort Follow-up: Mean 22 years, maximum 22 years (mortality outcomes); Mean 13 years, maximum 16 years for fatal BC cases within 10 years after diagnosis	n=392,135 serial participants, defined as women who participated in both of their last two scheduled screening examinations. Type of mammography: NR Number of screening intervals: 2	n=84,265 serial non-participants Women who did not participate in either of their last two scheduled screening examinations.	BC mortality
Dunn 2021⁵⁴, Australia Screening Program/Database: BreastScreen Australia	Participants: Women (aged 50–65 years) recorded on the Queensland Electoral Roll in the year 2000 Study design: Cohort Follow-up: Maximum 16 years	n= 187558 screened Women with a mammography record up to 31/12/2005. Women with a record of screening prior to 2000 were allocated to the screened group from the commencement of the accrual period. Type of mammography: NR Number of screening intervals: NR	n= 74792 unscreened Women with no mammography record from 2000 up to 31/12/2005. Women with no record of screening prior to the beginning of the accrual period contributed person-years in the non-screened cohort until the date of first attendance for screening during the accrual period.	BC mortality
Morrell 2017¹⁸, New Zealand Screening Program/Database: BreastScreen Aotearoa (BSA) programme	Participants: A cohort comprising all New Zealand women aged 45–69 years during 1999–2011 Study design: Cohort Follow-up: Maximum 11 years (2000-2011)	n= 542,234 ever screened Person-years of participation in screening are calculated from the time of first screen to the beginning of each successive year, or to the year of diagnosis for women diagnosed with breast cancer. Type of mammography: Two-view bilateral mammograms (initially), digital mammogram began in 2006	n=327, 623 never screened Women with no recorded screening participation in a given year, inferred by subtraction from ethnic- and age-specific census derived populations for that year, as provided by Statistics New Zealand	Breast cancer mortality

Study	Participants and Study Design	Intervention	Control	Outcomes
		Number of screening intervals: Up to 3		
Lund 2018⁴⁴, Norway Screening Program/Database: The Norwegian Breast Cancer Screening Program (NBCSP)	Participants: Women aged 49 to 79 during the first 9 years of national coverage of the NBCSP (2005-2013) were selected for the present analysis. Women living in Norway with no previous cancer diagnosis were included. Study design: Cohort Follow-up: Maximum 8 years (2005-2013)	n= 83,963 screened Women who have received at a NBCSP mammogram. Additionally, person years from women were categorised as unscreened until their first NBCSP mammogram, at which they were moved to the screened category. Type of mammography: Digital mammography Number of screening intervals: NR	n=9,974 never screened Women who had never taken a mammogram at time of recruitment	Overdiagnosis
Puliti 2017³⁷, Italy Screening Program/Database: Italian National Centre for Screening Monitoring	Participants: Nine health care districts in central and northern Italy participated in this study. The cohort included all women 50-69 years old who were invited to the first round of their local mammography screening programme. Study design: Cohort Follow-up: Median duration 11 years (IQR: 9-13); Total study period 1991-2009 with follow-up truncated at 13 years	n= 276,322 attenders Type of mammography: NR Number of screening intervals: At least one round (two rounds of screening invitations)	n=137,125 non-attenders Women who did not attend either of the first two screening rounds to which they received an invitation.	Stage at diagnosis
Weedon-Fekjaer 2014⁵⁵, Norway Screening Program/Database: Norwegian breast cancer screening programme	Participants: All Norwegian women aged 50 to 79 years between 1986 and 2009 were eligible for inclusion. Data were obtained from the Norwegian Cancer Registry and women were followed until they were censored (death, reached 80 years or they had reached the end of follow-up). Study design: Cohort	N= 2,407,709 person-years invited to screening Type of mammography: NR Number of screening intervals: NR Biennial invitations sent to women aged 50-69 years. Two-view screening mammograms are taken in breast diagnostic centres	n=12,785,325 person-years not invited to screening Person-time of those not invited to the Norwegian mammography screening programme, 1986-2009.	BC mortality

Study	Participants and Study Design	Intervention	Control	Outcomes
	Follow-up: Maximum follow-up 5-10 years after invitations to screening ended (1986-2009)	exclusively dedicated to the diagnosis and treatment of breast diseases.		
<p>Coldman 2014¹⁶, Canada</p> <p>Screening Program/Database: Canadian Breast Cancer Screening Initiative (CBCSI), including seven provincial screening programs: British Columbia, Manitoba, Ontario, Québec, New Brunswick, Nova Scotia, and Newfoundland and Labrador</p>	<p>Participants: Separate cohorts were assembled for each screening program, consisting of women who had at least one program screen between ages 40 and 79 years in the period between January 1, 1990, and December 31, 2009</p> <p>Study design: Population-based study</p> <p>Follow-up: Maximum 19 years (1990-2009)</p>	<p>Screening Cohort Province: British Columbia n=787815 Manitoba n= 132306 Ontario n= 797648 Québec n= 758912 New Brunswick n= 127039 Nova Scotia n= 162379 Newfoundland and Labrador n= 30373</p> <p>Type of mammography: NR</p> <p>Number of screening intervals: NR</p>	Referent rates were derived from nonparticipants in each province defined to be those not in, or before entry to, the participant cohort, n=NR	Standardized mortality ratios (SMRs) by age at entry, including 40 to 49 years
<p>Richman 2023⁴⁵, United States</p> <p>Screening Program/Database: SEER (Surveillance, Epidemiology, and End Results)-Medicare registry</p>	<p>Participants: Study included women aged 70 years and older by January 1, 2003, had no breast cancer detected before 2002 screening mammogram and had Medicare fee-for-service insurance through 2005.</p> <p>Study design: Cohort</p> <p>Follow-up: Median 13.7 years (IQR, 9.2 to 14.4 years) among women aged 70 to 74 years, 10 years (IQR, 5.8 to 13.9 years) for women aged 75 to 84 years, 5.7 years (IQR, 3.1 to 9.1 years) for women 85 years and older</p>	<p>n=44,485</p> <p>Type of mammography: Study adapted a validated algorithm that distinguishes screening mammograms from diagnostic mammograms based on Current Procedural Terminology (CPT) and Healthcare Common Procedure Coding System (HCPCS) codes.</p> <p>Number of screening intervals: NR</p>	<p>n=10,150</p> <p>Women who did not have a screening mammogram in three years after their 2002 mammogram were included in the non-screening group.</p>	Overdiagnosis
<p>Garcia-Albeniz 2020¹⁹, United States</p> <p>Screening program/Database: Medicare Data</p>	<p>Participants: Women aged 70-84 years who had a life expectancy of at least 10 years, had no previous breast cancer diagnosis, and underwent screening mammography. Women were US Medicare enrollees between 1999 and 2008 who have screening mammography the day they enter the trial.</p>	<p>N= 264,274</p> <p>"Continue screening" strategy (Women continue annual screening mammography (with a 3-month grace period and are excused from further screening after a breast cancer diagnosis)</p>	<p>n= 264,274</p> <p>"Stop screening" strategy (women do not have further screening after baseline)</p>	BC mortality, treatment-related morbidity, and overdiagnosis

<p>Blyuss 2023⁵⁶, United Kingdom</p> <p>Screening Program/Database: UK National Health Service Breast Screening Program</p>	<p>Participants: The population were those invited to BC screening. Cases were women who were diagnosed with primary breast cancer (invasive or in situ) in 2010 or 2011 and aged between 47 and 89 years. Controls were women sampled from the general population of those invited for screening and alive at the time of their corresponding case's date of diagnosis, matched on date of birth (within 1 month) and screening area at date of their case's diagnosis.</p> <p>Study design: Case-control</p>	<p>n= 144,699 ever screened (93,020 controls and 51,679 cases)</p> <p>Type of mammography: NR</p> <p>Number of screening intervals: Mean number of screening rounds, excluding those never screened (range): cases 3.4 (1.0–13.0); controls 3.3 (1.0–12.0)</p>	<p>n=18,447 never screened (12,633 controls and 5,814 cases)</p>	<p>Overdiagnosis</p>

Study	Participants and Study Design	Intervention	Control	Outcomes
	Follow-up: Maximum 2 3 years			
De Troeyer 2023²⁶, Belgium Screening Program/Database: Flemish population-based mammography screening program (PMSP)	Participants: The study population was all women aged 50-69 years and eligible for the Flemish PMSP between 2005-2012. Cases were women from the study population who died from BC between 2005-2017 and had the opportunity to be screened within the program at least once prior to diagnosis. For each case, four referents were randomly selected among the women of the study population who were still alive at the time of death of the corresponding case and who had the opportunity to be screened prior to the date of diagnosis of the case ('pseudodiagnosis' date). Study design: Case-control Follow-up: Outcomes assessed between 2005-2017; screening exposure period is within 4 years prior to BC diagnosis for cases/pseudodiagnosis for controls	N= 4217 screened (620 cases and 3597 referents) Type of mammography: Digital mammography introduced in 2005. Number of screening intervals: At least one	n= 3638 not screened (2687 referents and 951 cases)	BC mortality
Maroni 2021²⁵, United Kingdom Screening Program/Database: UK National Health Service Breast Screening Program	Participants: England-wide study of women who died of primary BC or matched controls invited to screening; women aged 47–89 years. Study design: Case-control Follow-up: Maximum 21 years (1990-2011)	n= 19946 (6547 cases and 13399 controls) screened Type of mammography: NR Number of screening intervals: 62.3% controls had 2+ rounds; 53.5% cases had 2+ rounds	n= 3544 never screened (1803 controls and 1741 cases)	BC mortality
van der Waal 2017²⁴, Netherlands	Participants: Case subjects were women who died of BC in Nijmegen between 1975 and 2008. Each case subject was	n= 1460 screened (220 cases and 1240 controls)	n= 538 not screened (425 controls and 113 cases)	BC mortality

Study	Participants and Study Design	Intervention	Control	Outcomes
<p>Screening Program/Database: Nijmegen (Dutch) screening program</p>	<p>matched to five control subjects, alive at the time of death of the matched case. All subjects had been invited to screening in the index round. The proportion of women with dense breasts among the interval cases ranged from 38.7% to 54.5%, and these proportions were always greater than for the screen-detected cases (ranged from 20.7% to 30.5%).</p> <p>Study design: Case-control</p> <p>Follow-up: Maximum 33 years (1975 – 2008)</p>	<p>Screening exposure was defined as attending the index screening round and/or the screening examination preceding the index round (pre-index round). This reflects the screening participation within the 4 years before (pseudo-)diagnosis.</p> <p>Type of mammography: Only screen-film mammograms</p> <p>Number of screening intervals: 1-2</p>		
<p>Massat 2016²², United Kingdom</p> <p>Screening Program/Database: UK National Health Service Breast Screening Program</p>	<p>Participants: Women residing in the London region, who had been invited to participate in the NHS BSP from 1988 onward. Cases were women who died of primary BC aged 47 to 89 years between 2008-2009, and who were diagnosed with primary BC (invasive) between the ages of 47 to 89 years after 1990. Each case was matched based on age and geographical area to 1-2 general population controls.</p> <p>Study design: Case-control</p> <p>Follow-up: Maximum 11 years (1998-2009; over 80% of women in our dataset selected were diagnosed from the year 2000 onward)</p>	<p>n=1991 screened at least once and invited at least once (649 cases and 1342 controls)</p> <p>n= 1286 screened >1 and invited at least twice (406 cases and 880 controls)</p> <p>Type of mammography: NR</p> <p>Number of screening intervals: Median (range) 2.0 (0-7) controls, 1.0 (0-8) cases</p>	<p>n=520 never screened and invited at least once (220 cases and 300 controls)</p> <p>n=299 never screened and invited at least twice (121 cases and 178 controls)</p>	<p>BC mortality</p>
<p>Beckmann 2015⁵⁷, Australia</p> <p>Screening Program/Database: BreastScreen South Australia (BSSA)</p>	<p>Participants: Cases were selected from the South Australian Cancer Registry (SACR) and consisted of all women diagnosed with breast cancer, between 2006 and 2010, who were aged</p>	<p>n= 17664 (3370 cases and 14294 controls) screened</p> <p>Type of mammography: Analogue screen-film technology</p>	<p>n= 7709 no screening records (1,213 cases and 6,496 controls)</p>	<p>Overdiagnosis</p>

Study	Participants and Study Design	Intervention	Control	Outcomes
	<p>between 45 and 85 years and resident in SA at the time of diagnosis. Five age-matched controls per case with the same month and year of birth were randomly sampled from the South Australian electoral rolls (ER) using an incidence density sampling approach.</p> <p>Study design: Case-control</p> <p>Follow-up: Maximum 21 years (1989-2010)</p>	<p>Number of screening intervals: At least 1 BreastScreen SA; Mean rounds of screening excluding never screened: 5.1 (1–18) cases; 4.9 (1–16) controls</p>		
<p>Pocobelli 2015²¹, Canada</p> <p>Screening Program/Database: Screening Program for Breast Cancer (SPBC)</p>	<p>Participants: Cases were women who died of BC at 50–79 years of age during 1990–2008 and who had continuous Saskatchewan healthcare coverage for at least 5 years prior to their first primary BC diagnosis (index date). For each case, 15 potential controls were randomly sampled, with the same birth year and the same duration of continuous health coverage.</p> <p>Study design: Case-control</p> <p>Follow-up: Maximum 13 years (1995–2008)</p>	<p>n=2833 (186 cases + 2647 controls) screened within the two years prior to and including the index date.</p> <p>SPBC began in selected regions of Saskatchewan. Women 50–69 years of age are identified from the population registry and are mailed a letter of invitation to receive a screening mammogram (women >70 years of age may attend, but they are not mailed a letter of invitation).</p> <p>Type of mammography: NR</p> <p>Number of screening intervals: NR</p>	<p>n=2677 not screened (315 cases and 2362 controls)</p> <p>No screening within the two years prior to and including the index date.</p>	<p>BC mortality</p>
<p>Paap 2014²⁰, Netherlands</p> <p>Screening Program/Database: Dutch breast cancer screening program</p>	<p>Participants: All women aged 50–75 years who received at least one invitation to the service screening program in the five participating screening regions. Cases originated from the source population and were defined as women who died from breast cancer in 2004 or 2005. Cases were individually matched to referents from the population invited to screening.</p> <p>Study design: Case-control</p>	<p>n= NR (overall 80.8% participation rate) screened</p> <p>Participated in the screening examination following their index invitation and/or the invitation in the screening round before the index invitation</p> <p>Type of mammography: NR</p> <p>Number of screening intervals: Maximum 2</p>	<p>n=NR (overall 19.2 non-participation rate) non-screened</p> <p>No participation in either the screening examination following their index invitation or the invitation in the screening round before the index invitation</p>	<p>BC mortality</p>

Study	Participants and Study Design	Intervention	Control	Outcomes
	Follow-up: Maximum 15 years (1990-2005)			
Ripping 2016²³, Netherlands Screening Program/Database: Nijmegen (Dutch) screening program	Participants: The case-control study was conducted within the population invited to the biennial mammographic screening program in Nijmegen, the Netherlands. Cases were defined as women who were aged 50 to 75 years at diagnosis and died from BC before 2013. For each case, five controls were matched based on age and invitation date to screening program. Study design: Case-control Follow-up: Maximum 38 years (1975-2013); analytic screening period 4 years before case diagnosis	N= 10,264 screened (1,541 cases and 8,723 controls) Type of mammography: Film before 2007, digital after 2007 Number of screening intervals: NR – Analytic period for screening was 4 years before the diagnosis of the case, covering 2 consecutive screening invitations.	n=3,328 unscreened (724 cases and 2,604 controls)	BC mortality
Katalinic 2020⁵⁸, Germany Screening Program/Database: German National mammography BC screening program	Participants: Study used anonymized individual data of female patients with first (incident) registered ductal carcinoma in situ (DCIS, ICD10: D05.1, representing about 95% of all in situ BCs) or invasive BC diagnosis (ICD-10:C50) Study design: Time-trend analysis Follow-up: NA	Active-screening period (2015-2016); n=NR Type of mammography: NR Number of screening intervals: NR The German screening program follows the European guidelines on BC screening and includes an invitation every two years.	Pre-screening period (non-screened; 2003-2004); n=NR	BC mortality (age-specific rate/100,000) by age group)
de Glas 2014³⁸, Netherlands Screening Program/Database: National Cancer Registry Netherlands	Participants: From the Netherlands cancer registry, we selected all patients aged 70-75 with a diagnosis of invasive and ductal carcinoma in situ BC between 1995 and 2011 Study design: Time-trend analysis	Active screening (2003-2011) time period; n= 3,394,055 person-years Type of mammography: NR Number of screening intervals: NR Study assessed the incidence of early stage and advanced stage breast	Pre-screening (1995-1997) time period; n=1,115,508 person-years	Stage at diagnosis for 70–75-year age group

Study	Participants and Study Design	Intervention	Control	Outcomes
	Follow-up: NA	cancer before and after implementation of the mass screening programme in women aged 70-75 years in the Netherlands.		
Parvinen 2015²⁸, Finland Screening Program/Database: Finish Cancer Registry	Participants: Since 1992, all Finnish women aged 50–59 years receive screening invitations every second year. The screening in Turku targeted female inhabitants aged 40–74 years. Study design: Time-trend analysis Follow-up: NA	Active-screening period (1987-2009); n= 468,195 person-years (1987-1997) and 541,096 person-years (1997-2009) Type of mammography: NR Number of screening intervals: NR The aim of this study was to evaluate the effectiveness of a large-scale screening programme for breast cancer (BC) in Turku, Finland. In Turku, women aged 40–49 years were invited at modified invitation intervals from 1987 to 2009. Women born in even years were invited annually, and those born in odd years, triennially.	Pre-screening time period (1976-1986); n= 430,462 person-years	BC mortality (for screening ages of interest 40-49 years)
Helvie 2014³⁹, United States Screening Program/Database: Surveillance, Epidemiology and End Results (SEER) database	Participants: Women aged 40 or greater in the U.S. that participated in the National Cancer Institute's SEER program Study design: Time-trend analysis Follow-up: NA	Active screening period (2007-2009); n=NR Type of mammography: NR Number of screening intervals: NR	Pre-screening time period (1977 to 1979); n=NR	Stage specific breast cancer (early stage, late stage)
Tabar 2019²⁹, Sweden Screening program/Database: the National Death Registry of the Swedish National Board of Health and Welfare	Participants: All women aged 40 to 69 years in the county of Dalarna, Sweden, during 39 years of the screening era (1977-2015). Study design: Time-trend analysis Follow-up: 10 years (for those diagnosed with BC through 2005) and 20 years (those diagnosed with BC through 1995)	n=NR Type of mammography: NR Number of screening intervals: NR In the service screening program, women aged 40 to 54 years are invited to mammography screening every 18 months, and those aged 55 to 69 years are invited to mammography screening every 24 months.	n=NR (Unscreened and Pre-screening control group) Unscreened population included women who did not participate in mammography screening. Pre-screening control means doing historical comparisons of the rate of death from breast cancer among women before	Breast cancer mortality

Study	Participants and Study Design	Intervention	Control	Outcomes
		The screening protocol is 2-view mammography.	the onset of the screening programs (1958-1976)

Colour coding: Green: Yes/Low; Yellow: Unclear/Moderate; Red: No/High. For the overall score, observational studies were colour-coded as “high”, “moderate” or “low” based on tallied scores of 75-100%, 50-75% of items, or below 50% of checklist items sufficiently met (Yes).

Table 2. Risk of bias ratings for Stage at Diagnosis Outcomes (Randomized Controlled Trials)

Study	Randomization	Allocation Concealment	Blinding (patients/personnel)	Blinding (outcomes)	Incomplete Outcome Assessments	Selective Outcome Reporting	Other	Overall Judgement
Swedish Two County (Kopparberg & Ostergotland) (Tabar 1995)	yes	no	unclear	yes	unclear	unclear	unclear	high
Malmö I (Nystrom 2016)	unclear	unclear	unclear	yes	unclear	unclear	yes	moderate
CNBSS 1 (Miller 2014)	no	unclear	unclear	yes	unclear	unclear	yes	high
HIP (Shapiro 1988)	unclear	unclear	unclear	no	unclear	unclear	unclear	high
Stockholm (Nystrom 2016)	no	no	unclear	yes	unclear	unclear	yes	high

Assessments performed using the Cochrane RoB-2 tool. The study is judged to be at overall high risk of bias if at least one domain had this result, moderate risk of bias if there were some concerns observed, and low risk of bias if all domains had this rating.

Table 3. Risk of bias ratings for Treatment-related Morbidity Outcomes (Randomized Controlled Trials)

Study	Randomization	Allocation Concealment	Blinding (patients/personnel)	Blinding (outcomes)	Incomplete Outcome Assessments	Selective Outcome Reporting	Other	Overall Judgement
CNBSS 1 (Miller 2014)	no	unclear	unclear	yes	unclear	unclear	yes	high
CNBSS 2 (Miller 2014)	no	unclear	unclear	yes	unclear	unclear	yes	high

Malmö I (Nystrom 2016)	unclear	unclear	unclear	yes	unclear	unclear	yes	moderate
Swedish Two County (Kopparberg) (Tabar 1995)	yes	no	unclear	yes	unclear	unclear	unclear	high
Stockholm (Nystrom 2016)	no	no	unclear	yes	unclear	unclear	yes	high

Assessments performed using the Cochrane RoB-2 tool. The study is judged to be at overall high risk of bias if at least one domain had this result, moderate risk of bias if there were some concerns observed, and low risk of bias if all domains had this rating.

Appendix 17 – Breast cancer mortality findings summary for exploratory analyses

Moderately increased risk (for family history)

The following data are extrapolations. We did not extract this data, however, used data from previously reported literature² and extrapolated.

a) 40 to 49 years

From RCT data, we extrapolated 0.44 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 1.28 to 1.51 fewer deaths per 1,000, depending on the study design.

b) 50 to 59 years

From RCT data, we extrapolated 0.79 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 2.33 to 2.76 fewer deaths per 1,000.

c) 60 to 69 years

From RCT data, we extrapolated 1.04 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 3.04 to 3.59 fewer deaths per 1,000.

d) 70 to 74 years

From RCT data, we extrapolated 1.47 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 4.31 to 5.10 fewer deaths per 1,000.

Moderately increased risk (for dense breasts)

The following data are extrapolations. We did not extract this data, however used data from previously reported literature³ and extrapolated.

a) 40 to 49 years

From RCT data, we extrapolated 0.53 fewer breast cancer deaths per 1,000 and from observational studies, values ranged from 1.54 to 1.82 fewer deaths per 1,000, depending on the study design.

b) 50 to 59 years

From RCT data, we extrapolated 0.95 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 2.77 to 3.28 fewer deaths per 1,000.

c) **60 to 69 years**

From RCT data, we extrapolated 1.23 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 3.61 to 4.26 fewer deaths per 1,000.

d) **70 to 74 years**

From RCT data we extrapolated 1.74 fewer breast cancer deaths per 1,000 and from observational studies values ranged from 5.10 to 6.03 fewer deaths per 1,000.

Appendix 18 - Sensitivity analysis by RoB - Breast cancer mortality RCTs

1. New analysis: Breast cancer mortality (RCTs, short-case accrual, stratified by age) Rated as moderate: Malmö I & II, AGE

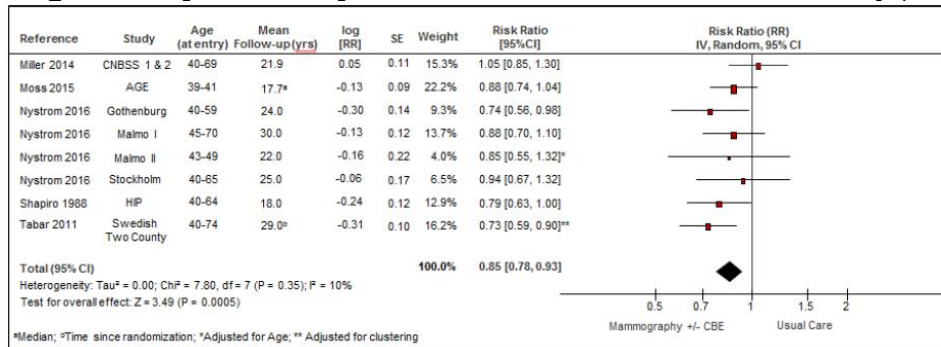

2. Original analysis 2018 systematic review: Breast cancer mortality (RCTs, short-case accrual, stratified by age)

3. **New analysis: Breast cancer mortality sensitivity analysis (RCTs, short-case accrual, all ages)**

4. **Original analysis 2018 systematic review: Breast cancer mortality (RCTs, short-case accrual, all ages)**

5. New analysis: All-cause mortality (RCTs, stratified by age)

6. Original analysis 2018 systematic review: All-cause mortality (RCTs, stratified by age)

Appendix 19 – Sensitivity analysis: Overdiagnosis RCTs removing high risk of bias trials

Mammography +/- CBE compared to Usual Care

Outcomes	Absolute effects		Relative effect (95% CI)	№ of participants (studies)	Quality of the evidence (GRADE)	Comments
	Incident rates with usual care (Assumed rate) ‡	Absolute risk (95% CI)				
Main analysis: Overdiagnosis invasive + in situ cancers (40-49 years) Range of follow-up (yrs): 9 to 15 years	17.4 per 1,000	1.57 more per 1,000 (from 0.35 more to 2.78 more)	RR 1.09 (1.02 to 1.16)	293,152 (2 ^{1,2} RCTs)	⊕⊕○○ LOW a,b,c,d,e	Using a threshold of 5, screening may lead to little to no difference in overdiagnosed cancers in individuals aged 40 to 49.
Other analysis: Overdiagnosis invasive cancers only (40-49 years) Range of follow-up (yrs): 9 to 15 years	16.2 per 1,000	0.49 more per 1,000 (from 0.65 fewer to 1.78 more)	RR 1.03 (0.96 to 1.11)	293,152 (2 ^{1,2} RCTs)	⊕⊕○○ LOW a,b,c,d,e	Using a threshold of 5, screening may lead to little to no difference in overdiagnosed invasive cancers in individuals aged 40 to 49 years
Main analysis: Overdiagnosis invasive + in situ cancers (50-59 years) Range of follow-up (yrs): 10 to 15 years	32.9 per 1,000	3.95 more per 1,000 (from 0.66 more to 7.9 more)	RR 1.12 (1.02 to 1.24)	132,231 (1 ¹ RCTs)	⊕⊕○○ LOW a,c,d,e,f	Using a threshold of 5, screening may lead to little to no difference in overdiagnosed cancers in individuals aged 50 to 59 years.
Other analysis: Overdiagnosis invasive cancers only (50-59 years) Range of follow-up (yrs): 10 to 15 years	31.2 per 1,000	2.81 more per 1,000 (from 0.62 fewer to 6.55 more)	RR 1.09 (0.98 to 1.21)	132,231 (1 ¹ RCTs)	⊕⊕○○ LOW a,c,d,e,f	Using a threshold of 5, screening may lead to little to no difference in overdiagnosed invasive cancers in individuals aged 50 to 59 years.

‡The assumed rate was calculated using the control event rates across included studies.

CI: Confidence interval

Bibliography: 1: Malmö I (Zackrisson 2006⁴¹); 2: AGE (Duffy 2020⁴³)

Mammography +/- CBE compared to Usual Care

Outcomes	Absolute effects		Relative effect (95% CI)	№ of participants (studies)	Quality of the evidence (GRADE)	Comments
	Incident rates with usual care (Assumed rate) ‡	Absolute risk (95% CI)				

GRADE Working Group grades of evidence

High quality: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate quality: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low quality: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low quality: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

Explanations

a. We downrated once for risk of bias. Randomisation and allocation concealment were not reported or unclear.

b. Not downrated for inconsistency; all point estimates in our pooled analysis lie to one side of our threshold.

c. Downrated once for indirectness. Data are from trials initiated in the 1960s-1990s and some trial estimates included participants outside the previously defined age decades (e.g., in the 40-49 age decade, one study included some individuals in their 50s).

d. Not rated down for imprecision. Clinical decision threshold set at 5.

e. According to Egger et al.¹¹, 10 trials are needed to assess publication bias. We cannot assess publication bias due to insufficient number of trials, therefore, we did not rate down for publication bias.

f. Only one trial evaluated, we did not downrate for inconsistency.

Forest plots

Age 40-49 (invasive + in situ)

Age 40-49 (invasive only)

Appendix 20 – Supplementary data on additional imaging (no cancers)

Part A: Additional imaging (no cancer) resolved by imaging or biopsy per 1,000 screens from provincial sources

1. Canada (excluding YT and NU), aged 50-69 by year (2004-2016), initial vs subsequent screen

Year	Per 1,000 screens	
	Initial screen	Subsequent screen
2004	120.5	60.5
2005	120.6	58.4
2006	120.2	56.4
2007	102.7	56.5
2008	111.5	58.3
2009	121.6	58.4
2010	131.4	60.3
2011	142	67.7
2012	150.4	70.3
2013	159.9	72
2014	160.6	71.7
2015	161.9	73.8
2016	166.6	75.2

Source: {FP=number of abnormal calls that were not confirmed as cancers per 1000 screens} from the CPAC 2020 report
Includes all provinces and territories, except YT and NU. Data prior to 2007 excludes AB.

Abnormal call rate: Data after 2014 do not include NS.

Invasive cancer detection rate: Data from 2013 to 2016 do not include NS and NB. MB data in 2016 might be underestimated.

2. Quebec, aged 50-69 by year (2011-2021), initial vs subsequent screen

Year	Per 1,000 screens		
	Initial screen	Subsequent screen	Total
2011	176.2	80.6	97.5
2012	197	91.5	110.3
2013	204.2	92.8	112.7
2014	204.3	90.8	109.6
2015	205.5	87.7	106.5
2016	220	88.7	109.5
2017	211.4	82.7	101.4
2018	216.7	81.9	100.6
2019	219.3	81.9	101.5
2020	210	83.7	97.4
2021	227.5	86.8	107.5
5 years average	217.4	83.8	102.5
10 years average	211.1	86.9	105.6

4. BC, ON, QC (different age groups) screened in 2017

Calculated additional imaging (no cancer) rates rate per 1000 screens (2017)	
British Columbia	84 (40-74 yrs)
Ontario	83 (50-74 yrs)
Quebec	101.4 (50-69 yrs)

Sources:

- BC Source : BC Cancer Breast Screening 2019 Program Results, September 2020, available from: <http://www.bccancer.bc.ca/screening/Documents/Breast-Screening-Program-Report-2019.pdf> (Table 12)
- BC additional imaging (no cancer) rate (2017) = 1- specificity = 1- 91.6% = 8.4%= 84 per 1000
- Quebec Source: Source: Programme Québécois de Dépistage du Cancer du Sein, released October 2023, available from : <https://www.inspq.qc.ca/sites/default/files/documents/pqdcs/tableaubordpqdcs.pdf>
- Quebec additional imaging (no cancer) rate per 1000 (Total) (2017)= reference rate - cancer diagnosis rate = 108 – 6.6 = 101.4 per 1000
- Ontario Source: The Ontario Cancer Screening Performance Report 2020, available from: <https://www.cancercareontario.ca/sites/ccocancercare/files/assets/OntarioCancerScreeningReport2020.pdf> (Tables 15-17)
- Ontario additional imaging (no cancer) rate (2017) = FP/(FP+TN) {reconstructed a 2x2 table}= (53,535 /643,564) x 100 = 8.3% = 83 per 1000

5. Nova Scotia (different age groups) followed from 2000-2011

Additional imaging (no cancer) rates per 1000 women screened	40-49 yrs	50-69 yrs	70-74 yrs
Nova Scotia (2000-2011) (based on the Nova Scotia breast screening program) {as reported}	210	143	76

Source: Nova Scotia Annual 2017 Report, available from:

https://breastscreening.nshealth.ca/sites/default/files/sites/default/files/annual_report2017.pdf (Table 11.3)

Note: This data is not directly comparable to the CPAC data as it is measured per 1000 women over 11 years

Part B: Additional imaging and biopsy (no cancer), per 1,000 screens

1. British Columbia, aged 40-74, by biopsy type in 2019

FPs per 1000 screens		Age group (40-74 years)
British Columbia (2019)	Needle Core	7.3
	Surgical	1.0
	Biopsy (core or surgical)	8.3

- Source: BC Cancer Breast Screening 2019 Program Results, September 2020, available from: <http://www.bccancer.bc.ca/screening/Documents/Breast-Screening-Program-Report-2019.pdf> (Figure 11)
- Calculations:
 - Total additional imaging and biopsy (no cancer) rate for core/FNA biopsies = $1944/266405 = 0.73\%$ or 7.3/1000
 - Total additional imaging and biopsy (no cancer) rate for open (surgical) biopsies = $269/266405 = 0.10\%$ or 1.0/1000
 - Total additional imaging and biopsy (no cancer) rate for biopsies = $2213/266405 = 0.83\%$ or 8.3/1000

2. British Columbia, aged 50-69, by biopsy type and initial vs rescreen, in 2020

Age 50-69	Biopsy type	Screen type	Per 1000 screens (2020)
British Columbia (2020)	Core	Initial screen	27.6
		Re-screen	5.4
	Open (surgical)	Initial screen	3.0
		Re-screen	0.8

- Source: BC Cancer Breast Screening 2019 Program Results, September 2020, available from: <http://www.bccancer.bc.ca/screening/Documents/Breast-Screening-Program-Report-2019.pdf> (Table 16)

3. Quebec, aged 50-69, resolved by open surgical biopsy, by initial vs rescreen and year (2011-2021)

Year	Per 1,000 screens		
	Initial screen	Subsequent screen	Total
2011	2.2	1	1.3
2012	2.7	1.1	1.4
2013	2.3	1.1	1.3
2014	2.3	1.1	1.3
2015	2.7	1.2	1.4
2016	2.7	1	1.3
2017	2.2	1	1.2
2018	2.9	0.9	1.2
2019	2.2	0.9	1
2020	2.3	1	1.1
2021	2.6	0.8	1
5 years average	2.4	0.9	1.1
10 years average	2.5	1	1.2

- Quebec Source: Source: Programme Québécois de Dépistage du Cancer du Sein, released October 2023, available from : <https://www.inspq.qc.ca/sites/default/files/documents/pqdcsc/tableaubordpqdcsc.pdf>

4. Nova Scotia, aged 50-69, resolved by core biopsy, by initial vs rescreen and year (2013-2016)

Age 50-69	Screen type	Per 1,000 women screened (by year)			
		2013	2014	2015	2016
Nova Scotia	Initial screen	49.8	31	29.5	39.4
	Re-screen	10.2	10.2	9.5	9.7

Source: Nova Scotia Annual 2017 Report, available from:

https://breastscreening.nshealth.ca/sites/default/files/sites/default/files/annual_report2017.pdf (Table 10.2)

Part C: Additional imaging with or without biopsy (No Cancer) rate using 2019-2020 CPAC data, ages 40-49

	BC 2019	BC 2020	PE 2019
Rate per 1000 screens ¹	129.4	127.5	108.4
Rate per 1000 screens estimated over 10 years (four rounds of screening) ²	517.6	510	433.6

Data source: Provincial Breast Cancer Screening Program

1. Additional imaging rate per screening round calculated by subtracting the cancer detection rates from the abnormal call rate. Abnormal calls were among individuals aged 40-49, who were screened within screening mammography program, by jurisdiction. The screening cancer detection rate (per 1,000) was used among individuals aged 40-49, who were screened within screening mammography program.
2. Additional imaging rate estimated using four rounds of screening over a 10-year period, assuming that the majority of women would receive a screen every 2-3 years.

Part D: Additional imaging with or without biopsy (No Cancer) using 2019-2020 CPAC data, ages 50-74

	All ages	50-59	60-69	70-74
Rate per 1000 screens ¹	77.1	90.6	67.6	63.3
Rate per 1000 screens estimated over 10 years (four rounds of screening) ²	308.4	362.4	270.4	253.2

Data source: Provincial Breast Cancer Screening Program

1. Abnormal calls were among individuals aged 50-74, who were screened within screening mammography program. Data include BC, AB, ON, NB, PE and NL. In PE, if a woman was screened a second time within 9 months of the previous screen, these screens were dropped because they were likely follow-ups to the first screens. Cancer detection rate (per 1,000) among individuals aged 50-74, who were screened within screening mammography program. Jurisdictions combined: Data include BC, AB, ON, NB, PE and NL. In NB and NL, screens that were lost to follow-up within 6 months of screening were not excluded.
2. Additional imaging rate estimated using four rounds of screening over a 10-year period, assuming that the majority of women would receive a screen every 2-3 years.

Part E: Additional imaging example calculations

Women aged 50-59 years using 2011-2012 CPAC data

1. Additional imaging with or without biopsy (no cancer):

Abnormal call rate per 1000 screens

- Initial = 156 per 1000
- Subsequent = 75 per 1000

Cancer detection rate (CDR) per 1000 screens

- Initial = invasive CDR + in situ CDR = 4.1 per 1000 + 1.2 per 1000 = 5.3 per 1000
- Subsequent = invasive CDR + in situ CDR = 2.7 per 1000 + 0.7 per 1000 = 3.4 per 1000

Calculated additional imaging rates (no cancer):

- Initial = $156 - 5.3 = 150.7$ per 1000
- Subsequent = $75 - 3.4 = 71.6$ per 1000

Rates over 10 years:

- Assuming started screening in this age decade (initial screen and three subsequent): $150.7 + (71.6 \times 3) = 365.5$ per 1000 in a 10-year period
- Assuming started screening in 40s (four subsequent screens): $71.6 \times 4 = 286.4$ per 1000 in a 10-year period

2. Additional imaging and biopsy (no cancer):

Non-malignant biopsy rate, initial screen (per 1,000 screens) = 20.7

Non-malignant biopsy rate, subsequent screen (per 1,000 screens) = 8.5

Rates over 10 years:

- Assuming started screening in this age decade (initial screen and three subsequent): $20.7 + (8.5 \times 3) = 46.2$ per 1000 in a 10-year period
- Assuming started screening in 40s (four subsequent screens): $8.5 \times 4 = 34$ per 1000 in a 10-year period

3. Additional imaging no biopsy (no cancer):

Additional imaging no biopsy (no cancer) = recall rate – (cancer detection rate + non-malignant biopsy rate)

Initial Screening:

- Additional imaging no biopsy (no cancer) = $156 \text{ per } 1000 - (5.3 \text{ per } 100 + 20.7 \text{ per } 1000) = 130 \text{ per } 1000$

Subsequent Screening:

- Additional imaging no biopsy (no cancer) = $75 \text{ per } 1000 - (3.4 \text{ per } 100 + 8.5 \text{ per } 1000) = 63.1 \text{ per } 1000$

Rates over 10 years:

- Assuming started screening in this age decade (initial screen and three subsequent): $130 + (63.1 \times 3) = 319.3$ per 1000
- Assuming started screening in 40s (four subsequent screens): $63.1 \times 4 = 252.4$ per 1000

Appendix 21 – Sensitivity analysis: Observational studies

The following sensitivity analysis includes our adherence to screen analysis for breast cancer mortality. There were notable differences between studies, and we teased out how removing certain studies impacted the overall estimate. A few items to note:

- Coldman reported standardized mortality, different from others that reported RR
- Morrel reported 3 totals based on screening types (ever screened, not screened regularly, and screened regularly)

A1) All adherence to screen papers: Coldman, Morrel, Duffy, Choi

The cohort adherence to screen: Morrel reported BC mortality for ever screened cohort (control group is never screened).

A2) All adherence to screen papers: Coldman, Morrel, Duffy, Choi

The cohort adherence to screen: Morrel reported BC mortality for not regularly screened cohort (control group is never screened).

A3) All adherence to screen papers: Coldman, Morrel, Duffy, Choi

The cohort adherence to screen: Morrel reported BC mortality for regularly screened cohort (control group is never screened).

B) Low risk of bias papers: Coldman, Duffy, Choi

C) Low risk of bias papers: Duffy, Choi (presenting relative risks only)
