85 Supplementary Methods

86 In this study, we analyzed data from the Netherlands Twin Register (NTR)¹ to examine the causal
 87 influences between smoking status and blood DNA methylation (DNAm) using MR-DoC models^{2,3}. In
 88 the current analyses, we included data from European-ancestry adult twins with both genotypic and
 89 DNAm data, comprising 2,577 individuals (67% female).

90

91 Genotypic Data, Principal Components Analysis, and Ancestry Outlier Pruning

92 The DNA samples included in the current study were genotyped on 3 SNP (single nucleotide
 93 polymorphism) microarray platforms: Affymetrix 6.0 (N= 2,399), Affymetrix Axiom (N= 83), and
 94 Illumina GSA NTR array (N= 95). Genotype calling was done following the manufacturer's protocols.
 95 Sample and variant quality control (QC), imputation, genetic principal component analysis (PCA), and
 96 ancestry assignment have been previously described⁴. Briefly, after QC and harmonizing variants across
 97 the three platforms, the data were aligned to the positive strand of *Genome Reference Consortium Human*
 98 *Build 37* (GRCh37) and then imputed against the European (EUR) super-population of the 1000 Genomes
 99 Project Phase-3 (KGP3)⁵, the Haplotype Reference Consortium (HRC)⁶ 1.1 (Ega version), and the
 100 Genome of the Netherlands Consortium (GoNL)⁷ reference panels. Using SmartPCA in EIGENSTRAT⁸,
 101 the first 20 PCs for the genotypic data were calculated in the KGP3 data, and the NTR samples were then
 102 projected onto the PC space based on the SNP weights. Samples identified as outliers in the PC space
 103 were then excluded.

104

105 Smoking Assessment at Blood Sampling

106 At the time of blood sampling for DNAm assessment, the participants answered the following
 107 questions about smoking in Dutch. The English translations are described in the main **Methods** section.

| | | |
|--|-----------------------------|--|
| Rookt u? | 1. Ja | 1a: hoelang rookt u al?jaar |
| | | 1b: hoeveel sigaretten/ shagjes per dag?sigaretten/ shagjes |
| | 2. Nee, wel in het verleden | 2a: hoelang is dat geleden?.....jaar |
| | | 2b: hoeveel jaren heeft u gerookt?.....jaar |
| | | 2c: hoeveel rookte u per dag (max)?sigaretten/ shagjes |
| | 3. Nooit | |
| Gerookt binnen laatste uur voor bloedafname? | 1. Ja 2. Nee 3. Nvt | |

108

109

110 Polygenic Risk Score of Smoking

111 The PRS of smoking was based on the European-ancestry summary statistics from the genome-
 112 wide association study (GWAS) of smoking initiation (lifetime regular smoking) by GSCAN (GWAS &
 113 Sequencing Consortium of Alcohol and Nicotine use)⁹, excluding the NTR from the meta-analysis.

114 As described in a previous study using the same PRS in the NTR⁴, the post-imputation SNPs
 115 from the merged best-guess three-platform data were QCed to satisfy the following criteria: MAF >0.01,

116 HWE p >0.00001, Mendel error rate < 1%, and genotype call rate over 98%. Furthermore, the imputation
117 info for the three platforms needed to be above 0.10, and the allele frequency between platforms after
118 imputation could not differ more than 2%, leaving a total of 7,551,860 post-QC SNPs for analysis. The
119 PRS was calculated using *LDpred* v0.9¹⁰, with HRC+GoNL as the LD (linkage disequilibrium) reference
120 panel. For estimating the target LD structure, we used a subset of unrelated individuals and a set of well-
121 imputed variants in the NTR. The parameter *ld_radius* was set by dividing the number of variants in
122 common (from the output of the coordination step) by 12000. For the coordination step, the median
123 sample size was used as the input value for N. For the LDpred step, we applied the following thresholds
124 for the fraction of variants with non-zero effects (in addition to the default infinitesimal model): --
125 PS=0.5, 0.3, 0.2, 0.1, 0.05, 0.01.

126 To determine the LDpred threshold that yielded the PRS with the highest predictive power for the
127 variables of interest (current vs. never and former vs. never smoking), we fitted logistic regression models
128 in R (v4.3.2) to estimate incremental R² on a liability scale. We first fitted a null logistic regression model
129 using the *glm()* function with *family=binomial(link='logit')* and a standard set of
130 covariates comprising age (linear and quadratic), sex, SNP microarray platform (dummy variables), and
131 the first ten genetic PCs (without including the PRS). Then, we fitted a full model with the PRS as an
132 additional independent variable. We estimated the liability-scale R² in both models and then the
133 difference in the two R² estimates as the variance in the outcome variable explained by the PRS
134 (controlling for the covariates). For both outcome variables (current and former smoking), the PRS with
135 the highest incremental R² was based on a threshold of 0.1 and thus retained for further analyses. The
136 PRS was residualized for the SNP microarray platform and the first ten genetic PCs using linear
137 regression models. The residuals were then standardized to have a mean of zero and an S.D. of one before
138 using it as an IV in the MR-DoC models.

198

199 Note. The “NearestGene” IDs from *Supplementary Table S1* were used as the input data for Metascape¹².
 200 Please refer to **Supplementary Tables S5-S6** for the corresponding annotation and enrichment results.
 201 As detailed in the Metascape manuscript¹², the program first identified all significant ontology terms,
 202 including GO/KEGG terms, canonical pathways, and hallmark gene sets. The significant terms (based on
 203 hypergeometric p-value <0.01 and >1.5-fold enrichment) were then clustered into a hierarchical tree
 204 based on Kappa-statistical similarities among their gene memberships. The tree was then cast into term
 205 clusters based on a threshold of 0.3 kappa score. The enrichment clusters and their underlying terms are
 206 marked as “Summary” and “Membership”, respectively, under the column *GroupID* in *Supplementary*
 207 *Table S24*. The “Summary” terms provide an overview of enriched, non-redundant ontology terms.
