Appendix B: Detail on Statistical Methods

EQ5D-5L Utility Index Scores

EQ5D utility scores (U) (higher score indicates a better quality of life) were transformed to disutility scores (D) (higher score indicates worse quality of life) using a simple linear transformation $D = 1 - U$ to give a distribution of values with a right skew which is more easily amenable for statistical analysis. Then, in order to examine the potential effects of the health care pathway covariates on the EQ5D disutility at 12-months while controlling for potential differences in baseline demographic and clinical risk factors, a generalised linear mixed model (GLMM) model of the form:

$$\ln (E[D]) = X\beta + Y\gamma + v$$

was constructed, assuming a gamma distribution of disutility and a log link. D is the EQ5D disutility index score, X are the covariates to be adjusted for, with coefficients β , Y are the indicators of health care pathway, with coefficients γ , and v is a random intercept at the level of the hospital. We run our statistical analysis in R and use the *glmmTMB* package (Brooks et al, 2017).

Healthcare Resource Use and Associated Costs

In order to examine the potential effect of the health care pathway covariates on the accumulated healthcare costs at 12 months post-discharge while controlling for potential differences in baseline demographic and clinical risk factors we construct a GLM model for cost with a Gamma distribution and log link:

$$\ln (E[C]) = X\beta + Y\gamma + v$$

where C is the health care costs and the right hand side is as previously specified for disutility.
