Short Title: Cardiovascular drug adherence during COVID-19

ABSTRACT

Background: Some studies have suggested that the COVID-19 pandemic negatively impacted patient adherence with chronic therapies. We designed this study to explore whether cardiovascular drug adherence patterns changed in chronically treated patients during the COVID-19 pandemic.

Methods: Retrospective cohort study examining drug dispensation data for all Alberta residents older than 18 years who were chronic users of at least one cardiovascular drug class, defined as receiving at least one prescription per annum for any agent in that drug class from March 15, 2017 to March 14, 2023 and 2 or more prescriptions within 365 days during either the pre-pandemic phase (March 15, 2018 to March 14, 2020) or the pandemic phase (March 15, 2020 to March 14, 2022). We calculated the proportion of days covered (PDC) for each drug class per patient and used generalized estimating equation logistic regression to estimate the effect of time period (pandemic versus pre-pandemic) on achievement of good adherence (PDC>0.8) after adjusting for age, sex, socioeconomic status, and comorbidities.

Results: We evaluated 548,601 chronic users of at least one cardiovascular drug class between March 15, 2018 and March 14, 2022. The most frequently dispensed cardiovascular drug classes were ACEi/ARB (67.6%), statins (53.8%), beta-blockers (21.0%), and calcium channel blockers (20.7%); the most frequent diagnoses were hypertension (77.2%), diabetes mellitus (30.6%), and ischemic heart disease (19.6%), although 55.4% of the patients had Charlson Comorbidity Index scores of 0. The mean PDC for cardiovascular drug use in our cohort was 85.7% (median 93%) pre-pandemic and 87.0% (median 94%) during the pandemic. The proportion exhibiting good

adherence (PDC>0.8) increased from 72.8% pre-pandemic to 75.4% during the pandemic ($p<0.001$). During the pandemic, users of cardiovascular drugs were more likely to exhibit good adherence (PDC>0.8) than they were in the pre-pandemic period: aOR ranged from 1.05 (95%CI 1.00-1.11) for mineralocorticoid receptor antagonists to 1.16 (1.15-1.17) for statins.

Conclusion: Chronic users of cardiovascular drugs exhibited higher adherence measures during the COVID-19 pandemic than prior to the pandemic.

It has long been recognized that adherence with proven efficacious therapies is associated with better patient outcomes and lower health care costs.[1-4] There are multiple reasons to hypothesize that the COVID-19 pandemic may have adversely affected patient adherence to long-term therapies: negative press and social media reports about some cardiovascular drugs increasing risk of COVID-19 (particularly ACEi and ARB), patient fear of going to pharmacies while COVID-19 was circulating in the community, many pharmacies reduced dispensation quantities to a maximum of 30 days from the usual 90 days to preserve the supply chain, and documented increases in drug shortages due to global supply disruptions. However, there is little empiric data published thus far. Three small surveys of selected patient samples suggesting adherence may have been substantially negatively impacted during the pandemic (with as many as one fifth of survey respondents reporting difficulty obtaining their medications early during the pandemic and up to a one third drop in adherence).[5-7] While an analysis of 27,318 American adults older than 40 years receiving antihypertensive prescriptions reported a drop in adherence from 65.6% pre-pandemic to 58.9% in the first 6 months after pandemic onset,[8] that analysis only included the period with the most widespread societal lockdowns and biggest reductions in access to outpatient care. Thus, we designed this study to explore whether cardiovascular drug adherence patterns in the Canadian province of Alberta changed during the COVID-19 pandemic beyond the initial few months – this is an important question to answer given the likelihood of future pandemics and thus the need to plan for the extent of resources that should be diverted to mitigate this issue during future pandemics.

METHODS

Design:

We conducted a retrospective cohort study examining drug dispensation data for all adult Albertans between March 15, 2017 and March 14, 2023. COVID-19 was declared a pandemic and emergency health measures were instituted in Alberta on March 15, 2020.

Data Sources:

The Alberta Pharmacy Information Network captures all drug dispensations in outpatient pharmacies in Alberta for patients of all ages. We linked the drug dispensation data with Alberta's Health Care Insurance Plan (AHCIP) registry files (which includes basic demographics as well as home address), physician claims database, the National Ambulatory Care Reporting System (which captures all emergency department visits in Alberta and includes up to 10 diagnoses), and the Canadian Institute for Health Information (CIHI-DAD) hospitalization database (which captures up to 25 diagnoses). Linkage was achieved using each individual's unique encrypted health identifier number and we were able to extract patient demographics, cardiovascular diagnoses, and comorbidity profiles from the linked datasets.

Study Samples – two time periods:

We compared cardiovascular drug dispensations for all Alberta residents older than 18 years in two time periods: 1) pre-pandemic: March 15, 2018 to March 14, 2020 and 2) pandemic: March 15, 2020 to March 14, 2022. Within each time period, we identified chronic users of each of the cardiovascular drug classes of interest using the same algorithm designed to avoid the pitfalls associated with defining a patient as a medication user on the basis of a single prescription or missing dispensations within the

12 months immediately before or after each time period. Thus, we defined chronic users as those receiving at least one prescription per annum for any agent in that drug class from March 15, 2017 to March 14, 2023 with 2 or more prescriptions on different days but within 365 days during either the pre-pandemic phase (March 15, 2018 to March 14, 2020) or the pandemic phase (March 15, 2020 to March 14, 2022). This algorithm was applied to each drug class separately and ensured that we were examining chronic users, not new users or discontinuing users. Lastly, we chose only those patient-drug class combinations which met the chronic users definition in both time periods to form our study sample. We excluded patients who were not registered with the Alberta Health Care Insurance Plan between March 15, 2017 and March 14, 2023, were younger than 18 at March 15, 2017, or who emigrated or died between March 15, 2017 and March 14, 2022.

Drug classes of interest:

We examined adherence with each of 6 drug classes (eTable 1): 1) angiotensin converting enzyme inhibitor or angiotensin II receptor blocker (ACEi/ARB), 2) statin, 3) calcium channel blocker (CCB), 4) beta blocker (BB), 5) thiazide and thiazide-like diuretics (including combinations with potassium sparing agents), and 6) mineralocorticoid receptor antagonist (MRA). For patients receiving multiple drug classes concomitantly, we calculated the patient's PDC for each drug class separately.

We excluded from consideration drugs that were not on the general formulary in Alberta and/or required special authorization processes in the timeframe studied, such as angiotensin receptor antagonist neprilysin inhibitors, sodium glucose cotransporter 2 inhibitors, glucagon-like peptide-1 receptor agonists, and direct oral anticoagulants. We

also excluded drugs prescribed for short timeframes (such as P₂Y₁₂ receptor antagonists after coronary interventions), drugs that could be purchased over the counter (such as aspirin), or drugs where the daily dose could vary based on test results (such as warfarin), fluid status (such as loop diuretics), or symptoms (such as nitrates).

Definitions of adherence:

We calculated adherence for each drug class using the ‘days supplied’ variable in the Alberta Pharmacy Information Network for all dispensations during each of the study time periods, recognizing that one patient could contribute data for several drug classes. Our primary analysis was the proportion of days covered (PDC) for chronic users of each drug class, calculated for each patient-drug dyad as the total number of days supplied for all dispensations of that drug class (regardless of dose) in the numerator and the number of days between March 15th, 2018 and March 14th, 2020 (731 days) and between March 15th, 2020 and March 14th, 2022 (730 days) as the denominator in the pre-pandemic and pandemic periods, respectively. We analyzed PDC as a continuous variable as well as in strata established in the literature (>80% vs. 40-80% vs. <40% for defining good vs. fair vs. poor adherence).[1,9]

Outcomes:

Our outcomes of interest were adherence at the level of each of the 6 drug classes and at the level of the patient (averaging across all drug classes dispensed for that patient), and we compared PDC and PDC strata (good, fair, or poor) in the pre-pandemic period with those in the pandemic period. Our primary outcome was the proportion of chronic users who exhibited “good adherence” (PDC>0.8) for each drug

class in the 2 years before (Mar 15, 2018-Mar 14, 2020) and after (Mar 15, 2020-March 14, 2022) the declaration of the COVID-19 pandemic in Alberta.

Comorbidities:

We used ICD-9 and ICD-10-CA case definitions previously validated in Alberta [10] for any hospitalizations, any emergency department visits, and any outpatient visits in the two years prior to and including the date of the first drug dispensation for that class in that patient to identify comorbidities for each patient (eTable 1). Of note, comorbidities identified only on outpatient visits to physician offices were considered as present only if at least two such claims were identified on two different days during the study timeframe. The Charlson Comorbidity index was calculated for each patient using the weights established by Shneeweiss et al.[11]

Statistical Analyses:

For each period (pre-pandemic and pandemic), chronic users of any of the 6-drug classes of interest were pooled together and we report descriptive statistics (means and standard deviations for continuous variables, counts and percentages for categorical variables) for chronic users in both time periods. The variables included demographics (age, sex, type of residence, material deprivation index based on home address), comorbidities (Charlson Comorbidity Index, ischemic heart disease, hypertension heart failure, diabetes), PDC, and PDC strata. A 100%-stacked bar chart was used to display differences in PDC strata for chronic users of each drug class between the pre-pandemic and pandemic time periods. For patients receiving multiple drug classes concomitantly, we calculated the patient's overall PDC as the average of their individual drug class PDC values.

To determine whether adherence changed from pre-pandemic to pandemic we used an adjusted logistic regression model for each medication class. The outcome was good adherence (PDC>0.8 versus not) and independent variables included time period (pre-pandemic, pandemic), sex (female, male), residence (urban, rural), material deprivation index (quintiles, a proxy for socioeconomic status), Charlson Comorbidity Index (0, 1-2, 3+), presence of heart failure, ischemic heart disease, hypertension, or diabetes (yes, no), and age (continuous). As each patient had a PDC record for both pre-pandemic and pandemic, we further adjusted the models for correlated data on the same user using generalized estimating equations (GEE). Thus, for each medication class the model estimated the adjusted effect of pandemic versus pre-pandemic on adherence.

A two-tailed p-value of less than 0.05 was considered significant. All analyses were conducted using SAS Version 9.4 (SAS Institute, Cary, NC). This study was approved by the University of Alberta Health Research Ethics Board (Pro00115481) with a waiver of individual patient consent as the investigators only had access to de-identified data.

RESULTS

There were 46,308,952 dispensations for the cardiovascular medications of interest between March 2018 and March 2022. After exclusion of prescriptions dispensed to patients who were not Alberta residents, were younger than 18, did not have at least 2 dispensations within the same drug class, or who died or emigrated during the study period, we identified 835,566 users of at least one cardiovascular drug

class in the 2 years prior to pandemic onset and 889,068 in the first 2 years of the pandemic (Figure 1). After excluding user-drug class combinations which were not dispensed in all years, our study cohort consisted of 548,601 patients who were chronic users of at least one cardiovascular drug class across both the pre-pandemic and pandemic periods. The most frequently dispensed cardiovascular drug classes were ACEi/ARB (67.6%), statins (53.8%), beta-blockers (21.0%), and calcium channel blockers (20.7%) – Figure 1. The most frequent diagnoses were hypertension (77.2%), diabetes mellitus (30.6%), and ischemic heart disease (19.6%), although 55.4% of the patients had Charlson Comorbidity Index scores of 0 (Table 1).

The number of prescriptions dispensed and the number of unique users per annum increased steadily across all study years for each drug class except thiazides (which were declining even prior to the pandemic) with no evident step changes at the time of pandemic onset in mid-March 2020 (Table 2). The annual number of dispensations for each drug class varied between 5 and 6 per user across all years studied (Table 2).

The mean PDC for cardiovascular drug use in our cohort was 85.7% (median 93.0%) pre-pandemic and 87.0% (median 94.0%) during the pandemic and the proportion exhibiting good adherence (PDC>0.8) increased from 72.8% pre-pandemic to 75.4% during the pandemic ($p<0.001$). The PDC varied minimally across drug classes (eTable 2), but was higher for all drug classes during the pandemic compared to pre-pandemic (eTable 2). The proportions of patients exhibiting good adherence

were higher during the pandemic than pre-pandemic for each of the drug classes we studied (Figure 2).

The multivariable logistic analyses with GEE revealed that the proportion of chronic users exhibiting “good adherence” (PDC>0.8) was significantly higher for all drug classes studied during the pandemic compared to prior (Table 3). During the pandemic, chronic users of cardiovascular drugs were 5% to 16% more likely to exhibit good adherence than they were in the pre-pandemic period (Table 3). Within each drug class-specific analysis, consistent predictors of better adherence were older age, higher socioeconomic status, rural residence, and a diagnosis of hypertension or diabetes mellitus. On the other hand, higher Charlson scores were associated with poorer adherence for all drug classes other than ACEi/ARB and the impact of sex and diagnoses of heart failure or ischemic heart disease varied between drug classes (Table 3).

DISCUSSION

Our main finding is that although adherence patterns with cardiovascular drugs varied slightly between classes, adherence within each drug class for chronic users was higher during the COVID-19 pandemic compared to the two years prior. This is in contrast to earlier surveys[5-7] and a cohort study focusing on just the first 6 months of the pandemic[8] which suggested that the COVID-19 pandemic may have profound negative impacts on medication adherence.

A recent systematic review of 12 published studies of medication adherence during the pandemic found that most studies evaluated medications for respiratory

diseases or inflammatory conditions, combined chronic, new, and transient users, and the data was not meta-analyzable given the variability in methods, metrics, and results.[12] For example, while one study showed improved adherence with inhaled bronchodilators for asthma patients during the pandemic,[13] another reported >20% drops in PDC for asthma control medications,[14] and a third found no change in refill rates for inhaled corticosteroids in patients with asthma during versus prior to the pandemic.[15]. However, the relevance of these studies to patients with cardiovascular diseases is questionable since there was an abundance of public health messaging emphasizing the dangers of COVID-19 in patients with pre-existing lung disease which may well have encouraged such patients to more rigorously adhere to their prescribed therapies. Two recently reported studies from Italy (only one of which was included in the systematic review mentioned above) reported minimal changes in adherence to statins, antihypertensive, or glucose lowering drugs during the first year of the pandemic, despite the fact Italy was particularly hard hit early in the pandemic.[16,17] A scoping review of barriers to antihypertensive medication adherence found that the COVID-19 pandemic did not introduce new barriers but did exacerbate pre-existing barriers of access and cost for disadvantaged populations.[18]

Although our study was able to capture all prescription medication dispensations from community pharmacies for all adults in the Canadian province of Alberta regardless of their disease or insurance status, there are some limitations to our work. For one, the databases analyzed included physician-assigned diagnoses but did not include details on clinical severity or physical measures like blood pressure or lipid levels, which precludes direct assessment of risk factor control or adequacy of disease

management. Second, our estimates of adherence may be over-estimates since we excluded new users and individuals who did not fill at least 1 prescription per annum over all study years, and using pharmacy refills to monitor medication intake fails to capture primary non-adherence (the failure of a patient to fill even the first prescription).[19] Moreover, pharmacy refill data may not align with actual patient consumption and is unable to capture temporary stops, pill splitting, dosage adjustments using existing dispensed supplies, or the use of free samples. We may also have potentially under-captured comorbidities during the initial stages of COVID-19 when patient healthcare encounters decreased (although this is less than might be expected as we have previously documented that the frequency of outpatient encounters stayed largely the same pre/during pandemic because of the introduction of virtual billing codes allowing telephone follow-up).[20] Our study also does not assess changes in adherence associated with spikes and troughs in the number of COVID-19 cases, hospitalizations, or deaths which affected different areas at different times and may also have influenced adherence.

In conclusion, contrary to what surveys and very early studies suggested may happen, drug dispensations and patient adherence were not adversely affected by the COVID-19 pandemic, at least in the Canadian province of Alberta. In fact, we found that chronic users of cardiovascular drugs exhibited slightly higher adherence during the COVID-19 pandemic than prior to the pandemic. Thus, it would appear that processes initiated early in the pandemic to address the impact of societal lockdowns and reduced access to in-person outpatient care (principally the introduction of physician billing codes for the provision of virtual care) as well as the efforts of various professional

societies, including the American Heart Association, to combat misinformation about the risks of cardiovascular drugs vis-à-vis COVID-19 had their intended effect and should help guide our responses to future pandemics.

ACEi – angiotensin-converter enzyme inhibitor, ARB - angiotensin II receptor blocker, BB - beta blocker, CCB - calcium channel blocker, MRA – mineralocorticoid receptor antagonists, PDC – proportion of days covered, SD – standard deviation, IQR – interquartile range, CCI – Charlson Comorbidity Index.

46,308,952 cardiovascular medication dispensations

PRE-PANDEMIC

PANDEMIC

922,040 users of a cardiovascular medication

986,428 users of a cardiovascular medication

- Excluded 86,474 (9.4%) individuals
- Without 2 dispenses for the same drug class (4194, 0.45%)
 - Not-registered with AHCIP (30750, 3.33%)
 - Age is missing or < 18 years (3372, 0.37%)
 - Migrated out of Alberta by 14MAR2020 (6108, 0.66%)
 - Died before 14MAR2020 (42050, 4.56%)

- Excluded 97,360 (9.7%) individuals
- Without 2 dispenses for the same drug class (4354, 0.44%)
 - Not-registered with AHCIP (33072, 3.35%)
 - Age is missing or < 18 years (3898, 0.40%)
 - Migrated out of Alberta by 14MAR2022 (7286, 0.74%)
 - Died before 14MAR2022 (48750, 4.94%)

835,566 users of at least one cardiovascular drug class (at least 2 dispensations on 2 different days within 365 days)

889,068 users of at least one cardiovascular drug class (at least 2 dispensation on 2 different days within 365 days)

STUDY POPULATION
548,601 **chronic** users of at least one cardiovascular drug class both pre- and during the pandemic (at least 2 dispensations on 2 different days within 365 days AND at least 1 dispensation per year 2018-2022)

PDC Distribution by Drug Class (P1 = pre-pandemic; P2 = during pandemic)
