the spatial expansion, to detect and respond to Oropouche virus outbreaks promptly. 108 Introduction

109 Oropouche virus (OROV; *Orthobunyavirus oropoucheense*) is an arthropod-borne virus classified within
the order *Bunyavirales*, family *Peribunyaviridae* and genus *Orthobunyavirus* (1). It is present as a
negative-sense, 110 the order *Bunyavirales, family Peribunyaviridae* and genus Or*thobunyavirus* (1). It is present as a
negative-sense, single-stranded RNA genome that is divided into three segments based on size: S
(small), M (medium) and 111 negative conse, single-stranded matrix and the matrix and the single-stranded into the server on size: If (small), M (medium) and L (large). These segments encode four structural proteins: the nucleocapsid, two external gl 112 two external glycoproteins, and the RNA polymerase (2). OROV was first identified in 1955 in
Oropouche, a village in Trinidad and Tobago (3). Since then, the virus has been responsible for numerous 113 The Thermal glycoproteins, and the RNA polymerase (2). The Party member in 1956 in 1968 in 1968 in the Chopouche, a village in Trinidad and Tobago (3). Since then, the virus has been responsible for numerous outbreaks, mos 114 Outbreaks, mostly within the Amazon Basin, where it is found among forest animals such as non-human
primates, sloths, and birds (4). The midge *Culicoides paraensis* is the primary vector for human
transmission. Infection 115 primates, sloths, and birds (4). The midge *Culicoides paraensis* is the primary vector for human
transmission. Infection with OROV causes Oropouche fever, which typically presents as fever, headache, 116 primates, sloths, and birds (4). The midge c*ulicoides particlies* is the primary vector for human
transmission. Infection with OROV causes Oropouche fever, which typically presents as fever, headache,
muscle and joint pai 117 muscle and joint pain (5). The majority of human infections present as mild to moderate disease and
resolve within a week, although rare cases can lead to complications like aseptic meningoencephalitis
(6). 118 resolve within a week, although rare cases can lead to complications like aseptic meningoencephalitis (6). 119 120

121

Historically, OROV outbreaks were largely restricted to the Amazon region, with about 30 outbreaks reported in Latin America until recent years (7). However, new epidemiological data show a 122 ks reported in Latin America until recent years (7). However, new epidemiological data show a
increase in Oropouche fever cases in Brazil, Cuba (N=74), Bolivia (N=356), Colombia (N=74), and 123 marked increase in Oropouche fever cases in Brazil, Cuba (N=74), Bolivia (N=356), Colombia (N=74), and
3 124 marked increase in $\frac{1}{\sqrt{2}}$, $\frac{1}{\sqrt{2}}$, $\frac{1}{\sqrt{2}}$, $\frac{1}{\sqrt{2}}$, and $\frac{1}{\sqrt{2}}$, an

125 Peru (N=29), minimum cases related cases reported in Italy, Spain, and Germany, an engineering from Cuba,
highlighting that it's becoming recognized outside the region (8, 9). Notably, Brazil alone reported a total
number 126 127 significant rise in transmission (10-12). In 2024, Brazil also reported the first three fatal cases associated
with OROV infection, raising concerns among health authorities (13). OROV has also recently appeared
in histori 128 with OROV infection, raising concerns among health authorities (13). OROV has also recently appeared in historically non-endemic Brazilian regions outside the Amazon, including in the far south and, importantly, in some ur 129 in historically non-endemic Brazilian regions outside the Amazon, including in the far south and,
importantly, in some urban centers on the east coast (13). As is the case for other arboviruses (14),
recent changes in dise 130 im historically non-endemic Brazilian regions of the Amazon, including in the far sound and,
importantly, in some urban centers on the east coast (13). As is the case for other arboviruses (14),
recent changes in disease e 131 important changes in disease ecology, such as deforestation, urbanization, human mobility and climate
change, are some of the possible drivers of its recent emergence in the Amazon region (15). Local

Genome sequences were obtained from all five Brazilian macro-regions (North, South, Northeast, South East and North East), revealing north-to-south viral movement across the country 292 Example sequences were carried from all the several matrix regions (North, South, St., South East and North East), revealing north-to-south viral movement across the country
1). The most frequent symptoms observed among th 293 The Hortheast, South East and Northeast, South Countries countries and the country (Figure 1). The most frequent symptoms observed among the patients were fever, myalgia, and headache. These symptoms were consistently repo 295 experiencing arthralgia. In addition to the common symptomatic presentations, our study identified
three fatal cases associated with OROV infection. Notably, these fatalities occurred in young adult
patients with no report 296 experiencing arrangia. In addition of the common symptomatic presentation, our study identified
three fatal cases associated with OROV infection. Notably, these fatalities occurred in young adult
patients with no reported 297 three fatal cases are fatal cases as the clinical course resembled severe dengue, with shock, bleeding, and extensive coagulopathy. Without the extensive lab evaluations due to the ongoing OROV outbreak in the region, thes 298 patients with the reported comorbidities in all cases, the clinical connective resemble servere denguing shock, bleeding, and extensive coagulopathy. Without the extensive lab evaluations due to the ongoing OROV outbreak i 299 OROV outbreak in the region, these deaths would likely have been misclassified as Dengue Fever rather 300 than OROV. The detection of these fatal cases suggests that OROV may have a broader clinical impact
than previously understood, warranting further investigation into the factors contributing to severe
disease outcomes. Poi 301 than previously understood, warranting further investigation into the factors contributing to severe disease outcomes. Point mutations were identified in all three fatal cases. In the M segment, amino acid changes included 302 disease outcomes. Point mutations were identified in all three fatal cases. In the M segment, amino acid
changes included I to V at position 13, M to I at position 642, A to T at position 752, and R to K at
position 1342. 303 discussed included I to V at position 13, M to I at position 642, A to T at position 752, and R to K at position 1342. In the L segment, mutations were found at amino acid positions 857 (T to A), 1634 (K to E), and 2206 (N 304 position 1342. In the L segment, mutations were found at amino acid positions 857 (T to A), 1634 (K to E), and 2206 (N to D). Further in-depth analyses are required to determine whether these mutations play any role in the 305 E), and 2206 (N to D). Further in-depth analyses are required to determine whether these mutations play any role in the pathogenesis and severity of OROV infections. There was seemingly no evidence that symptoms varied wit 306 play any role in the pathogenesis and severity of OROV infections. There was seemingly no evidence that 307 308

The sequencing procedures yielded an average coverage of 97.7% for segment S, 98.5% for symptoms varied with age or gender (Figure 31).
The sequencing procedures yielded an
segment M, and 98.32% for segment L (Table S1). 309 The sequencing procedures yielded an average coverage of events of eigenemics, serverally for the sequence of
The sequence of 98.32% for segment L (Table S1). Using a Generalized Additive Model similar to the one
The syste 310 segment M, and 98.32% for segment L (Table 31). Osing a Generalized Additive Moder similar to the one
used for other arboviruses (30), we generated response curves for resulting sequence coverage
dependent on sample CT. As 311 dependent on sample CT. As expected, both observed (Table S1) and estimated sequence coverage
were negatively correlated with CT value (Figure 2a). Segment M overperformed and segment S
underperformed in sequence coverage 312 were negatively correlated with CT value (Figure 2a). Segment M overperformed and segment S
underperformed in sequence coverage independently of CT value (albeit only marginally). Segment M
was the least sensitive to CT va 313 were negatively correlated with CT value (Figure 2a). Segment M overperformed and segment S
underperformed in sequence coverage independently of CT value (albeit only marginally). Segment M
was the least sensitive to CT va 314 underperformed in sequence correnge independently of CPT value (albeit only marginally). Segment in
was the least sensitive to CT value, showing consistent sequence coverage across sample CT. The states
of Bahia and Minas 315 was the least sensitive to CT value, showing consistent sequence coverage and set cample coverage for model
output, with consistently lower sequence coverage for Bahia and higher coverage for Minas Gerais,
independently of 316 output, with consistently lower sequence coverage for Bahia and higher coverage for Minas Gerais, independently of sample CT and across all genome segments (Figure S2). Prolonged intervals between symptom onset and sample 317 independently of sample CT and across all genome segments (Figure S2). Prolonged intervals between
symptom onset and sample collection were associated with increased CT values (Figure 2b), suggesting
a decline in viral RNA 318 independently of sample CT and across all genome segments (Figure S2). Frolonged intervals between
symptom onset and sample collection were associated with increased CT values (Figure 2b), suggesting
a decline in viral RNA 319 symptom onset and sample collection were associated with increased CT values (Figure 2b), suggesting
a decline in viral RNA quantity and consequently sample quality over time, underscoring the critical
importance of minimi 320 importance of minimizing the time between symptom onset and sample collection to ensure the acquisition of high-quality sequencing data. Additionally, considering the segmented nature of the OROV genome, we investigated th 321 acquisition of high-quality sequencing data. Additionally, considering the segmented nature of the OROV 322 genome, we investigated the potential presence of reassortment and recombination among the three 323 different genome segments. We identified 21 reassortment events: 17 separating the S and M 324 segments, 7 separating the S and L segments, and 11 separating the M and L segments. 325 segments, 7 separating the S and L separating the S and L separation of S and L separation of M and L separation
S and L separation of M and L separation of

392 Discussion

393 The spread of the novel reassortant OROV lineage between 2022 and 2024 in the Brazilian
Amazon region highlights the potential for this virus to emerge and the role of ecological and human
factors in its dissemination (11, 394 Factors in its dissemination (11, 12). Our study, along with recent findings (11, 12), underscores the importance of genomic surveillance and phylogenetic analysis in tracing the origin and movement of viral pathogens. The 395 factors in the intermination (11, 11, 12). Our study, along the recent financy (11, 12), and the unique sumplem
importance of genomic surveillance and phylogenetic analysis in tracing the origin and movement of
viral patho 396 importance of genomic surveillance and phylogenetic analysis in the origin and movement of virtual pathogens.

Surveillance and the phylogenetic analysis from our study revealed that the OROV sequences sampled

basal seque 397 between 2022 and 2024 fell into a highly supported monophyletic group, with origins tracing back to a
basal sequence from Tefé, Amazonas, Brazil, sampled in 2015. This indicates a likely Amazonian origin
for this clade. Th 398 basal sequence from Tefé, Amazonas, Brazil, sampled in 2015. This indicates a likely Amazonian origin
for this clade. These findings are consistent with the emergence of a novel reassortant lineage
containing the M segment 399 basal sequence of a non-
tor this clade. These findings are consistent with the emergence of a novel reassortant lineage
containing the M segment from viruses detected in the eastern Amazon region and the L and S
segments 400 for this clade. These finally are consistent with the energies of a novel reasonant ineage
containing the M segment from viruses detected in the eastern Amazon region and the L and S
segments from viruses found in Peru, Co 401 comming the M segment from There is accessed in the section change in the leader segments from viruses found in Peru, Colombia, and Ecuador (10, 11). This reassortant lineage appears
to have emerged in the central region o 402 segments from viruses from viruses found in the central region of the Amazonas state between 2010 and 2014, demonstrating a
Iong-range silent dispersion during the latter half of the 2010s. Our study identified approximate 403 to have emerged in the central region of the central region of the Amazonas long-range silent dispersion during the latter half of the 2010s.Our study identified approximately 21 reassortment events among the different gen 404 lous consideration of the different genome segments, supporting the role of reassortment in the
evolutionary history of OROV (11). It is possible that this contributed to the virus's ability to adapt to
new ecological nich 405 evolutionary history of OROV (11). It is possible that this contributed to the virus's ability to adapt to
new ecological niches and hosts, fueling its spread across different regions of Brazil. The sharp increase
in OROV 406 407 in OROV cases in different Brazilian regions along with the concurrent rise in real-time RT-PCR testing,
reflects heightened surveillance and detection efforts underscoring the widespread concern and the
proactive measures 408 in the cases in the concept Brazilian regions and different RT-PCR the concern and the proactive measures taken to monitor this emerging pathogen. 409 proactive measures taken to monitor this emerging pathogen.
Our genome-based surveillance approach revealed a clear north-to-south movement of the 410

proactive measures taken to move the corrective measure filters our genome-based surveillance approach revealed a
irus within the country. The peak of OROV transmissions coinc 411 Out in the country. The peak of OROV transmissions coincided with the rainy season in the Amazon
And uggesting that environmental factors may play a major role in the virus's transmission dynamics.
The virus of the south m 412 basin, suggesting that environmental factors may play a major role in the virus's transmission dynamics.
Deforestation and climate change have contributed to the spread of OROV beyond the Amazon basin
(32, 33). The alterat 413 basin, suggesting that environmental factors may play a major role in the virus's transmission dynamics.
Deforestation and climate change have contributed to the spread of OROV beyond the Amazon basin
(32, 33). The alterat 414 (32, 33). The alteration of ecosystems through deforestation disrupts natural habitats and promotes the
migration of vectors, such as midges, into new areas (33). Climate change exacerbates this by altering
weather pattern 415 (32). The alteration of vectors, such as midges, into new areas (33). Climate change exacerbates this by altering
weather patterns and creating favorable conditions for vector proliferation (34). These ecological
changes f 416 weather patterns and creating favorable conditions for vector proliferation (34). These ecological
changes facilitate the movement of OROV from its traditional Amazonian confines to other regions of
Brazil and beyond. Rece 417 changes facilitate the movement of OROV from its traditional Amazonian confines to other regions of
Brazil and beyond. Recent studies have shown that increased deforestation rates and rising
temperatures in the Amazon basi 418 changes facilitate in depend. Recent studies have shown that increased deforestation rates and rising
temperatures in the Amazon basin correlate with the expanded range of vector species capable of
transmitting OROV (11, 3 419 temperatures in the Amazon basin correlate with the expanded range of vector species capable of
transmitting OROV (11, 35-40). This north-to-south dissemination pattern highlights the importance of
addressing environmental 420 transmitting OROV (11, 35-40). This north-to-south dissemination pattern highlights the importance of addressing environmental and climate-related factors in controlling the spread of arboviruses. The prolonged cryptic cir 421 addressing environmental and climate-related factors in controlling the spread of arboviruses. The
prolonged cryptic circulation of the virus emphasizes the critical need for robust, active screening
programs to monitor an 422 addressing environmental and climate-related factors in controlling the spread of showst, active screening
programs to monitor and control the spread of such pathogens effectively. The detection of three fatal
cases associ 423 programs to monitor and control the spread of such pathogens effectively. The detection of three fatal
cases associated with Oropouche virus (OROV) infection, even in patients without reported
comorbidities, suggests that 424 programs associated with Oropouche virus (OROV) infection, even in patients without reported
comorbidities, suggests that the clinical impact of OROV might be more significant than previously
understood. This necessitates 425 comorbidities, suggests that the clinical impact of OROV might be more significant than previously
understood. This necessitates further investigations into adverse pregnancy outcomes and the potential 426 comorbidition in the comorbidition of the current and the potential independence and the potential
for vertical transmission of OROV. On August 3rd, the Brazilian Ministry of Health (BrMoH) confirmed
the first fetal death 427 Intertion the intertional in an anti-singulation into an enterty programs, the current and inspection.
