

1

2 **Figure S6.** Impact of OCT focus on model performance. (A) 24-2 VF thresholds, (B) 10-2 VF
3 thresholds, (C) 24-2 MD, and (D) 10-2 MD. The horizontal axis represents OCT focus in 1 D
4 increments, and the vertical axis represents MAE. Each panel shows boxplots of MAEs for each OCT
5 focus increment, with linear regression lines. Slight increases in MAEs are observed for myopic eyes
6 in thresholds (A and B) and 10-2 MD (D). Linear regression analysis revealed slopes of -0.015 dB/D
7 (24-2 VF thresholds), -0.048 dB/D (10-2 VF thresholds), 0.018 dB/D (24-2 MD), and -0.021 dB/D
8 (10-2 MD). These small slopes quantify the minimal impact of refractive errors on model
9 performance, with slightly more pronounced effects for 10-2 VF thresholds. Overall, the model
10 demonstrates robust estimation capabilities across various refractive errors.
11 OCT = optical coherence tomography; VF = visual field; MD = mean deviation; D = diopter; MAE
12 = mean absolute error.
