22 **Abstract**

23

24 Manual counting of platelets, in microscopy images, is greatly time-consuming. Our
25 goal was to automatically segment and count platelets images using a deep learning approach,
26 applying U-Net and Fully Convolutional Network (FCN) modelling. Data preprocessing was
27 done by creating binary masks and utilizing supervised learning with ground-truth labels. Data
28 augmentation was implemented, for improved model robustness and detection. The number of
29 detected regions was then retrieved as a count. The study investigated the U-Net models
30 performance with different datasets, indicating notable improvements in segmentation metrics
31 as the dataset size increased, while FCN performance was only evaluated with the smaller
32 dataset and abandoned due to poor results. U-Net surpassed FCN in both detection and counting
33 measures in the smaller dataset Dice 0.90, accuracy of 0.96 (U-Net) vs Dice 0.60 and 0.81
34 (FCN). When tested in a bigger dataset U-Net produced even better values (Dice 0.99, accuracy
35 of 0.98). The U-Net model proves to be particularly effective as the dataset size increases,
36 showcasing its versatility and accuracy in handling varying cell sizes and appearances. These
37 data show potential areas for further improvement and the promising application of deep
38 learning in automating cell segmentation for diverse life science research applications.

39

40 **Author Summary**

41 Deep Learning can be used with good results for automatic cells images segmentations,
42 reducing the time applied by scientists to this task. In our research platelets images were
43 automatically segmented and counted using by applying U-Net and Fully Convolutional
44 Network (FCN) modelling. Data preprocessing was done by creating binary masks and
45 utilizing supervised learning with ground-truth labels, after data augmentation. U-Net
46 surpassed FCN in both detection and counting measures in a smaller dataset. The U-Net model

47 proves to be particularly effective as the dataset size increases, showcasing its versatility and
48 accuracy in handling varying cell sizes and appearances. Our study shows potential areas for
49 further improvement and the promising application of deep learning in automating cell
50 segmentation for diverse life science research applications.

51

52

53 **Introduction**

54

55 In recent years, cell segmentation has emerged as a critical component in numerous
56 research fields, including bioinformatics, cell biology, and computational biology [1–3]. Deep
57 convolutional neural networks (CNNs) have revolutionized visual recognition tasks,
58 outperforming traditional methods across various domains [4]. By utilizing CNNs, deep
59 learning algorithms have demonstrated the ability to accurately identify and count cells in
60 biomedical images [5]. However, the conventional use of CNNs in classification tasks does not
61 fully address the complexities of cell segmentation in microscopy images, where pixel-level
62 localization is crucial [6].

63 Cell segmentation, the process of delineating cell boundaries in microscopy images, is
64 a critical step for morphological analysis and downstream quantification of biological
65 structures. Since 2015, a range of deep CNN architectures have achieved breakthrough results
66 on standard cell segmentation benchmarks [7]. Early networks like U-Net by Ronneberger et
67 al. [8] introduced a symmetric encoder-decoder structure to propagate multi-scale contextual
68 information, which became highly influential. Other top designs utilized pre-trained
69 classification backbones like Visual Geometry Group by Simonyan and Zisserman [9] or
70 Residual Networks by He et al. [10], to effectively initialize deep models. More recent
71 techniques further incorporated elements like atrous convolutions by Chen et al. [11] and

72 generative adversarial training [12] to capture both local details and global consistency.
73 Powered by ever larger annotated datasets, these latest CNNs have surpassed human experts
74 on nuclei segmentation and approaching expert inter-observer agreement on challenging cell
75 contouring tasks [13,14].

76 However, substantial obstacles prevent the real-world adoption of deep learning
77 segmentation tools. Cell images exhibit high appearance variability under different
78 experimental conditions, with artifacts like missing cellular boundaries, that easily confuse the
79 models [15]. Complexities such as cell-cell interactions, for example overlapping cells or cell-
80 background interactions, also pose difficulties [16]. Such data heterogeneity issues combined
81 with label noise and inconsistencies during manual segmentation, poses several segmentation
82 challenges [17,18]. Furthermore, while state-of-the-art results are reported on some curated test
83 images, deep networks frequently fail to generalize across different imaging setups without
84 extensive retraining [19].

85 To overcome these limitations, recent works have proposed techniques to improve
86 model robustness. Generative and reconstructive approaches to incorporate unlabelled data
87 during training can enhance generalizability [20]. Assessment of remaining errors to guide
88 annotation and data augmentation can mitigate dataset bias [21]. Through focused
89 incorporation of these sophisticated regularization, adaptation, and interaction techniques, deep
90 CNNs may eventually fulfil their promise for practical automated cell segmentation [22,23].

91 Nowadays, both U-Net, as a particular type of FCN and FCN in general are known as
92 CNN architectures to be employed in microscopy and biomedical image analysis, with U-Net
93 being a particular type of FCN [24,25]. While FCN utilizes a classification network like
94 ImageNet by Krizhevsky et al. [26], and U-Net was built on fully convolutional network (FCN)
95 with hourglass topology [8,24]. Semantic segmentation framework is based on a bounding box-
96 based segmentation pipeline that extracts the foreground from a given region of interest. It

97 focused on image local patterns and extracted complex image information at various scales. It
98 has proven to be successful in biomedical applications and has gained popularity in many
99 research studies in cell detection [5,27] and cell segmentation [28,29].

100 The recent growing of deep learning applications for microscopic analysis is
101 revolutionizing the process of classifying, counting and segmenting cells [30]. These tasks
102 which traditionally were performed by humans and are very time consuming, have a high
103 potential of success to be fully automated through deep learning algorithms with good results
104 [31]. Furthermore, manual segmentation also introduces a high degree of user subjectivity and
105 variability which may have an impact on the experimental results obtained [31].

106 Therefore, this research aims to build an automated system for platelets segmentation
107 and respective size determination, on microscopy images, by creating a mask that allows the
108 platelets detection and counting.

109

110 **Results**

111 **Model evaluation**

112

113 Experiments with the smaller dataset (293 images) were performed both with FCN
114 and with U-Net, while only the two bigger datasets (1172 and 4688 images) were used with U-
115 Net. Experiments with FCN were abandoned after experiments with the smallest data set due
116 to its inferior comparative performance. Different methodologies of threshold were used for
117 the two types of networks. FCN used a method of segmentation by the Sobel operator, while
118 U-Net used binarization of the image to create ground-truth masks for segmentation.

119

120 **FCN model evaluation**

121

122 Data pre-processing within the FCN model generated masks as segmented images from
123 Sobel operator at a kernel or threshold value of 7, as shown in Fig 1. As it can be seen the Sobel
124 operator tends to enhance the edges of the platelets [32].

125
126
127
128

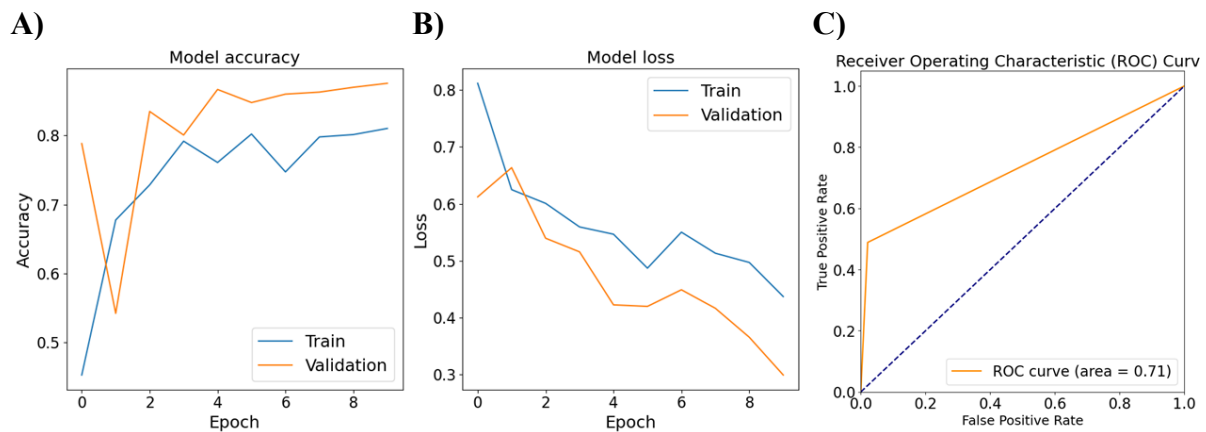

129

130 **Fig 1. Identification of Sobel Segmented Images within FCN model.** Platelets ($2 \times 10^7/\text{ml}$)
131 were spread on fibrinogen for up to 45 minutes, before fixation, staining, and imaging using a
132 Zeiss Axiovert Fluorescent microscope (oil x63 NA 1.4 objective). (A) Image is representative
133 of control conditions. (B) Representative image segmented by enhanced Sobel operator.

134

135 The FCN model was evaluated with the complete iteration of 10 epochs utilizing a
136 processing time of 1206 seconds and resulted in an accuracy of 0.81, reaching an Area Under
137 the Curve (AUC) of the Receiver Operating Characteristic (ROC) of 0.71. This and the loss
138 function can be seen in Fig 2. For visually inspecting the cell segmentation and the model's
139 performance, the ground truth masks were compared with the masks predicted by the model.
140 But the model failed to demonstrate or produce predicted cell counts as it resulted in MPE of
141 55.44%.

142

143

144 **Fig 2. Plots of FCN model evaluated on 293 images. (A) training and validation loss; (B)**

145 **accuracy; and (C) AUC-ROC.**

146

147 **U-Net model evaluation**

148

149 In the U-Net model instead of the Sobel operator, binary masks of the platelets images,
150 named ground-truth masks were created preprocessing using a threshold of 25 for image
151 binarization. An example of the ground truth mask, and of the image from which were created
152 are shown in Fig 3.

153

154

155 **Fig 3. Identification of ground truth marks within U-Net model. Platelets (2x10⁷/ml) were**

156 **spread on fibrinogen for upto 45 minutes, before fixation, staining and imaging using a Zeiss**

157 Axiovert Fluorescent microscope (oil x63 NA 1.4 objective). (A) Image is representative of
158 control conditions. (B) Representative image with the corresponding ground-truth masks.

159

160 The U-net model was pre-trained with generated masks and a complete iteration of 10
161 epochs was monitored on both the training and validation datasets resulting in an accuracy of
162 0.96. A lower MAE of 2.6% suggests that model's predictions are close to the true values,
163 reflecting accuracy in pixel-wise predictions, as shown in Fig 4.

164

165

166 **Fig 4. Identification of platelet segmentation with U-Net model.** Platelets ($2 \times 10^7/\text{ml}$) were
167 spread on fibrinogen for up to 45 minutes, before fixation, staining and imaging using a Zeiss
168 Axiovert Fluorescent microscope (oil x63 NA 1.4 objective). (A) Image is representative of
169 control conditions; (B) representative image with ground-truth masks; (C) predicted images
170 from U-Net model; (D) corresponding heat maps. All images have a dimension of 256×256
171 pixels.

172

173 Lastly, the U-Net model was evaluated by rotating 1172 images into specified degrees
174 of 90, 180, and 270, creating a combined dataset of 4688, and their corresponding masks were

175 generated at threshold of 25. The training accuracy reached 0.98 and the validation loss
176 continued to improve across epochs reaching an AUC of the ROC of 0.99, as shown in Fig 5.

185 **accuracy, (B) loss and (C) AUC-ROC.**

186

187 **Cell counting by U-Net**

188

189 Following the training of the U-Net, the subsequent phase involved cell count drawn
190 from a dataset encompassing 4688 images. The training employed a L2 loss function,
191 incorporating aleatoric uncertainty for cell counts (Fig 6), and optimization was carried out
192 using the Adam optimizer with a learning rate of $1E-4$ and a batch size of 8 (Fig 8). The
193 estimation of cell sizes in the predicted masks, as shown in Fig 7, for each segmented cell

194 (region) was calculated in terms of number of pixels it occupies at region (bounding box size)
195 with a threshold of 50.

Cell segmentation and quantitative evaluation by U-Net

225 The outcomes derived from the evaluation of U-Net models on the three dataset groups
226 indicated a very positive correlation between the size of the dataset and the positive results,
227 achieving higher values for the bigger dataset, as it can be seen in Table 1. In the biggest dataset
228 the maximum values are accuracy of 0.98, recall 0.98, precision of 0.99, IoU of 0.99 and Dice
229 of 0.99. Additionally, a concurrent reduction in both dice loss and sparse categorical cross-
230 entropy loss was observed, as the employed loss functions exhibited a robust interdependence
231 and displayed an inverse relationship with accuracy (Figs 5A and 5B). Following the specified
232 criteria, the most favourable U-Net configuration [33] involved five encoding and decoding
233 blocks. This assessment also extended to the examination of the number of filters in the initial
234 encoding block, revealing a doubling of filters with each subsequent block and a corresponding
235 halving with each decoding block. The optimum number of filters, within the investigated
236 parameters, was identified as 64 in the first encoding block. This U-Net has been used for other
237 types of segmentation tasks [33] but was revealed more successful in the application to platelets
238 segmentation than another U-Net model initially tested, and which is more commonly used in
239 cell segmentation [8].

240 Table 1 elucidates the performance outcomes, throughout several metrics, of cell
241 segmentation derived from the evaluation of the test set for each model. The evaluation was
242 conducted across distinct datasets characterized by varying numbers of images, with the U-Net
243 model serving as the segmentation architecture.

244

245 **Table 1.** Cell segmentation performance results computed for each model.

Model	Dataset (number of images)	Dice	IoU	Precision	Recall	Accuracy	Training Time (s)
U-Net	293	0.90	0.82	0.85	0.95	0.96	1766
	1172	0.98	0.97	0.99	0.97	0.97	6417
	4688	0.99*	0.99*	0.99*	0.99*	0.98*	6354
FCN	293	0.60	0.42	0.92	0.44	0.81	1206

246 * Best scores

247

248 Across the dataset comprising 293 images, the U-Net model achieved a Dice coefficient
249 of 0.90, indicating a substantial agreement between the predicted and ground-truth
250 segmentation masks. The IoU, measuring the overlap between the predicted and true
251 segmentations, was 0.82. The precision, reflecting the positive predictive value, was observed
252 to be 0.85, while recall, gauging the model's ability to capture all positive instances, exhibited
253 a value of 0.95. The overall accuracy, encompassing both true positive and true negative
254 predictions, was 0.96. It is worth noting that using the optimum threshold of 0.25 assures huge
255 cut-offs and enforces only detections with high confidence, as this was the only value in which
256 all the platelets were correctly included in the binarization of the im-aging. A too low threshold
257 would increase the areas beyond the platelets area, while a too high one would confuse darker
258 platelets as background. Although desirable, this behaviour increases false negatives, as fewer
259 platelets are spotted resulting in accuracy down-fall, with the impact of false negatives being
260 twice as large as it is in Dice of 0.90, explaining the disparity between these two metrics. The
261 single significant exception is accuracy, which U-Net architectures excels at. This is most likely
262 owing to an "over-detection" tendency. Nonetheless, the FCN counterparts outperform this
263 tendency by significantly im-proving accuracy and precision reported at 0.81 and 0.92,
264 respectively.

265 As the dataset size increases to 1172 and 4688 images, the U-Net model demonstrated
266 notable improvements in performance metrics. The Dice coefficient increased to 0.98 and 0.99
267 respectively, indicating enhanced segmentation agreement, while IoU rises to 0.97 and 0.99,
268 depicting increased overlap between predicted and true segmentation. The consistently high
269 values across various evaluation metrics sustained the U-Net model's effectiveness in handling
270 datasets with varying cell sizes and appearances, as reported in Table 1. The model exhibited

271 further refinement in segmentation due to a series of deconvolutional layers that reconstructed
272 the output image from the extracted features as the training data increased. In contrast, FCN
273 models do not have analogous shortcut paths to retain and fuse low-level information through
274 the network architecture. IoU of 0.42 proves that as sequential encoder-decoder flows, FCN
275 faces more challenges restoring spatial de-tails from compressed latent bottles when built on
276 smaller datasets, as it was seen from the results of the comparison of both models in the 293
277 images set where both were tested. For this smaller dataset, U-Net model's MAP of 0.99
278 denoted exceptional precision across the dataset, suggesting a minimal number of false
279 positives and high relevance in the predicted outcomes. MAE of 0.002 and MPE of -0.050
280 indicated a close alignment between the model's prediction with a negative sign showing a
281 slight underestimation on average. For the FCN Model, the results suggest that it performs
282 reasonably well in terms of precision, with MAP scores around 0.8365. However, there is room
283 for improvement in reducing the absolute and percentage errors in pixel-wise predictions, as
284 indicated by the MAE and MPE values of 0.1828 and 0.5544 respectively.

285

286 **Discussion**

287

288 Deep Learning use for imaging classification, segmentation and counting has some
289 advantages over this work being done by humans. First convolutional neural networks are more
290 consistent than humans, as they will (1) classify images identically each time, (2) do not
291 introduce differences in the procedure (3), are a great time saver [33]. Given all the
292 improvement possibilities for imaging classification, segmentation and counting, it is of crucial
293 importance to find suitable methods to support or replace humans in these tasks where it is
294 possible [34,35].

295 From our research we are led to believe that the U-Net model could be very promising
296 to aide in effective analysis of platelets microscopic images. This U-Net [33] model uses the
297 notion of deconvolution by [4,33] analysis and synthesis. The analytical path follows CNNs
298 structure as shown in Fig 8 and the expansion step of the synthesis path consisted of an up-
299 sampling layer followed by a deconvolution layer. It is found that the most essential aspect of
300 U-Net is the ability to create shortcut connections between layers of equal resolution in the
301 analysis path and the expansion path. These connections supply the deconvolution layers with
302 critical high-resolution features [36,37].

303 The studies undertaken in this research stand on the implementation of two specific
304 design choices which were found to significantly enhance the performance of the model.
305 Firstly, the incorporation of ground truth masks, and second the application of a U-Net model.
306 The incorporation of ground truth masks penalizes errors occurring on cell boundaries and in
307 densely populated regions, proving to be instrumental in promoting precise segmentation,
308 particularly in scenarios involving closely situated objects [38,39]. Similarly to what was
309 reported in the bibliography [40,41] in our comparative analysis the U-Net model stands out as
310 the most effective network outperforming the FCN (Table 1) across all performance metrics
311 apart from the precision and training time, when both U-Net and FCN were applied to the
312 smallest dataset. Given this difference in performance, only U-Net was applied to the bigger
313 datasets with excellent results, in all metrics, and without much computational time added. It
314 is important to note that as the dataset in-creased four-fold in complexity the processing times
315 of the U-Net model remained similar (at 6417 and 6354 sec respectively). This a very
316 advantageous characteristic when searching for a model to train [42].

317 This success seems to be due to the combination of (1) ground truth masks and (2) U-
318 Net architecture which demonstrated high accuracy in cell count predictions and adheres to the
319 conservative counting requirement that underscores that precise cell counts are a result of

320 accurate object detection rather than a mere balancing effect between false positives and false
321 negatives [43].

322 In our work instead of applying a standard U-Net five-layer convolutional module
323 already in use for cell segmentation [8], a four-layer module was used to meet the segmentation
324 task and avoid excessive parameters [33].

325 Here an encoder with a succession of convolution and max pooling layers characterized
326 the network, with a mirrored sequence of transposed convolutions in the decoding layer. The
327 U-Net model learns the crucial features of the images after encoding, and to segment the image
328 needs to decode them. Each convolutional block in the decoder has the same settings as those
329 in the encoder. After each convolutional block, the image is up-sampled twice using bilinear
330 interpolation to make it larger. Then, a skip connection links it to the corresponding feature
331 map in the encoder. It utilizes a 1x1 convolutional layer after last set of decoder blocks to
332 construct the final segmented image and for the conversion of RGB to grayscale.

333 The layer of convolution network in the FCN model is a three-dimensional data array,
334 with each layer representing an image with height x width x depth pixels and colour channels
335 [24]. The image is the initial layer, with receptive fields representing the image's positions.
336 Convolution, pooling, and activation functions operate on local input regions and are based on
337 translation invariance. The inclusion of bounding boxes around regions facilitated the
338 quantitative assessment of segmentation accuracy (Fig 6).

339 Additionally, when considering uncertainty predictions, over 80% of ground-truth
340 counts were found to fall within the model's predicted 95% confidence interval across our 750-
341 image test (examples showed in Fig 6). This visualization is invaluable for understanding the
342 segmentation performance, assessing the accuracy of cell delineation, and providing insights
343 into potential areas for improvement. The inclusion of cell sizes and not only of the cells

344 counting, enhances the interpretability of the segmentation results by providing quantitative
345 information about the segmented platelets within the predicted masks (Fig 7).

346 The absence of foreground masks for out-of-focus images in the dataset hinders
347 counting performance, suggesting the potential for enhancement through the inclusion of such
348 masks. However, challenges may persist [16,44,45], particularly in cases of overlapping cells
349 (platelets) [46,47], a difficulty even confounding human experts. To address this, a plausible
350 strategy involves incorporating the original image as supplementary input to the counting
351 network. Additionally, another approach could entail utilizing randomly cropped image patches
352 and robustly estimating counts by averaging density across multiple patches, akin to the
353 methodology proposed by Oñoro-Rubio and López-Sastre [48].

354 Notably, similarly to other works the strategic enhancements we introduced in
355 comparison to the original U-Net architecture, specifically the integration of a learned
356 transformation and the inclusion of a residual block with 3×3 filters, seem to significantly
357 contribute to the model's superior performance [49,50]. Lastly, it becomes evident that even
358 instances of misidentification possess a certain degree of subjectivity, residing within the
359 nuanced boundaries of interpretability for borderline cases (examples showed in Fig 6).

360 Finally, it was shown how aleatoric losses can be used to estimate uncertainty in cell
361 counting for failure cases where ground-truth is outside of some acceptable tolerance [51]. Our
362 work is limited by the requirement of annotated datasets, in which the bias of the labelling can
363 be introduced.

364 Similarly to the U-Net model, FCN's architecture consists of multiple convolutional
365 layers to collect features from input data, and pooling layers minimize the spatial dimensions
366 of the data to capture the most significant information. But given our results when comparing
367 it with the U-Net model it was shown not to be the most optimum model.

368 In summary, the proposed approach, with the U-Net and ground truth masks, has
369 demonstrated its robustness to be applied for automating prevalent operations across various
370 life science research applications. Consequently, this strategy holds the potential to yield
371 significant advantages in terms of expediting studies and mitigating operator bias, both within
372 individual experiments and across diverse experimental contexts.

373

374 **Material and Methods**

375

376 This study proposed the implementation of the U-Net and FCN models for accurately
377 segment platelets, in microscopy images. Platelets are dense and adherent cells, causing extra
378 difficulties in the segmentation task [52,53]. In Fig 8 is depicted the overall procedure devised
379 using U-Net for segmenting, counting, and calculating the area of the platelets, as this was the
380 best performing system. All the procedures begun with the pre-processing of original
381 microscope cell images, and preparation of the databases by augmentation of the original
382 datasets. The preprocessing of the images was done primarily by adjusting image size of the
383 images, followed by segmentation procedures. After detecting the platelets, the final counting
384 is obtained as the number of connected pixels in the post-processed output. The study design
385 decisions, such as the chosen threshold, were all aimed at reducing false negatives and
386 promoting accurate segmentation, and images quality highly influences the training of the
387 network, and the segmentation results possible to be achieved by it.

388

389

390 **Fig 8. Diagram of the methodology approach for segmenting platelets in biomedical**
391 **images using the U-Net. Adapted from [54].**

392

393 **Dataset**

394

395 The suggested framework was assessed using a dataset gathered by the Centre for
396 Biomedicine, Hull York Medical School, University of Hull, UK [55]. The original database
397 includes 293 microscopy images that have been carefully classified by skilled experts. These
398 datasets showed platelets clustered together with low-contrast cell borders. Cell size and
399 appearance varied between datasets. The first dataset consisted in 293 microscopy cell images
400 of human blood platelets after different treatments: with Zinc, Milrinone, and Mil-rinone +
401 Zinc (in a total of 299, excluding five duplicates and one blank image). From the ethical
402 perspective, no image annotation tool was used as the dataset does not contain an-notations or
403 labelling. To increase the dataset size, were created two datasets with 1172 and 4688 cell
404 images by data augmentation (splitting and rotating the original images). The original dataset

405 of 293 images was an 8-bit 3-channel jpeg of 2752x2208 pixels each (Fig 9). The dataset of
406 1172 images were created by splitting 293 images into 4 quadrants resulting in 3-channel 1376
407 x 1104 pixels each. Applying rotating methods, the dataset was increased from 1172 to 4688.
408

409
410 **Fig 9. A and B). Two different samples of microscopy cell images from the original dataset.**

411 Images with 2752x2208 pixels.

412

413 **Data preprocessing**

414

415 Firstly, the dataset of 293 images was inspected and duplicates were removed to create
416 this new cleaned database. Following, contrast was enhanced using Contrast Limited Adaptive
417 Histogram Equalization (CLAHE) with clip limit of 3, which is a contrast enhancement
418 technique that prevents over-amplification of noise. The data augmentation technique
419 introduced new patterns into the training dataset, which made the training procedure more
420 resistant to over-fitting, and was applied with randomized rigid geometric changes, scaling,
421 and colour values (grey), where each training sample was rescaled, and then randomly spun
422 before flipping it. A standard split of 80-20 train/test was used for all the final models, with the
423 different tested datasets.

424 For both FCN and U-Net models masks were created for the segmentation but the
425 procedure to create these masks was different. For the FCN model, masks were created as
426 segmented images from Sobel operator at kernel value of 3, 5, 7 and 9 as appropriate. A larger
427 kernel size increases sensitivity to broader edges but might reduce localization accuracy for
428 finer details. The function in the sobel operator calculates the gradient magnitude by taking the
429 square root of the sum of squared horizontal and vertical Sobel responses (sobel_x and sobel_y
430 respectively) providing a combined measure of edge strength in both directions.

431 For visually inspecting the cell segmentation performed by the FCN Model and the
432 model's performance, the ground truth masks were compared with the masks predicted by the
433 model. For cell counting from the segmented images, multiple threshold values of 0.10, 0.15,
434 0.25, and 0.5 were tested for minimum area or region of interest for creating bounding boxes.

435 For the U-Net model ground-truth masks were created by binarization of the images.
436 This binarization happened from the threshold value which allowed all the cells to be binarized.
437 As well here several binarization threshold values were tested, namely 0.05, 0.15, 0.25, 0.30
438 and 0.50. 0.25 was considered the optimum threshold value for creating the ground truth masks
439 as all the platelets would be binarized in a close area.

440 In the training phase, a supervised learning framework used the ground-truth la-belled
441 images, as samples of desirable outputs that the model should learn to generate. In the case of
442 image segmentation, such targets take the form of binary images (masks), with white (0) and
443 black (1) pixels, representing the objects to segment and the background, respectively (Figure
444 1). To the cleaned images was then applied a second threshold using automatic histogram
445 shape-based algorithms. Region properties were calculated, and bounding boxes were drawn
446 around regions with an area exceeding the specified second threshold applied of 0.5 to match
447 the true mask and to eliminate the smaller particles or noise.

448

449 **Model architecture and training**

450

451 FCN architecture consists of an encoder-decoder structure. The encoder extracts
452 features from the input images through convolutional and pooling layers, while the decoder up-
453 samples these features to generate pixel-wise predictions. Skip connections were incorporated
454 to preserve spatial information during upsampling.

455 The FCN architecture chosen comprised 2 layers of 4 convolutional blocks with 64 and
456 128 filters in both the encoder and decoder section, with 2 max-pooling layers in the encoder,
457 2 Up-sampling layers and 2 concatenation layers (one for each decoding block), and one final
458 convolutional layer with a sigmoid activation function. The model was compiled using the
459 Adam optimizer and binary cross-entropy loss function and the model was trained on the
460 smaller dataset. A validation split of 20% was used to monitor the model's performance during
461 training.

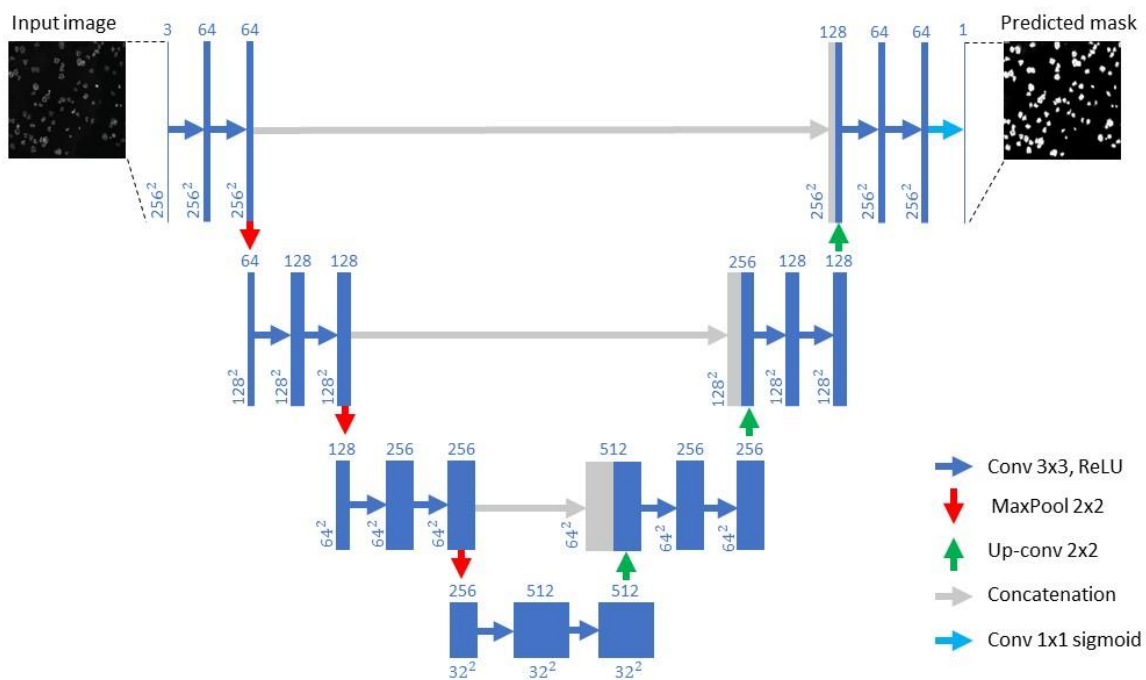

462 The model was evaluated on training and validation datasets with the complete iteration of 10
463 epochs but abandoned due to less successful results than the U-Net model applied. The U-Net
464 model used in our study [33], started with a defined input layer, accommodating image size of
465 256x256 pixels with 3-color channel. For deeper feature extraction in encoder portion, a series
466 of convolutional layers with 64, 128, and 256 filters of size 3x3 interspersed with rectified
467 linear unit (ReLU) activations and max-pooling operations progressively reducing spatial
468 dimensions, followed by a middle bottleneck layer of 512 filters to capture contextual
469 information and a decoder segment with similar layers as encoder segment, which
470 progressively up samples feature maps and concatenates them with feature maps from the
471 corresponding encoder layers, enhancing localization precision.

472 Each of these convolutional blocks in the encoder, employed edge filling for each
 473 convolutional layer to maintain the feature map and the ReLU function, and is expressed in
 474 equation 1.

$$ReLU = \begin{cases} x & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \quad (1)$$

476
 477 The final layer employed a sigmoid activation, followed by Adaptive Moment
 478 Estimation (Adam) optimizer with learning rate of $1E-4$, and binary cross-entropy loss which
 479 quantifies the dissimilarity between predicted and ground-truth segmentation maps.

480

481

482

483 **Fig 10. U-Net applied architecture.** Adapted from [33].

484

485 In this scenario, image segmentation required unannotated data with ground-truth labels
 486 resulting in an unsupervised or weakly supervised image segmentation approach, and the

487 construction of a loss function capable of assessing the quality of segments or clusters of pixels
488 is the key difficulty. The model was compiled with binary cross-entropy as the loss function.

489 In our study the U-Net model (Fig 10) was trained and tested on 234 and 59 cell images
490 and ground-truth masks, respectively.

491

492 **Metrics for model performance evaluation**

493

494 Intersection over Union (IoU) or the Jaccard Index (J), is a widely used metric in se-
495 mantic segmentation, where A and B represent the true and predicted segmentation maps,
496 respectively (Equation 1), and Dice (Equation 2).

497

$$IoU = J(A, B) = \frac{|A \cap B|}{|A \cup B|} \quad (2)$$

498

$$Dice\ coefficient = 2 * \frac{|A \cap B|}{|A| + |B|} \quad (3)$$

499

500 To calculate the overall detection of platelets (True Positive (TP)), it is assumed that
501 the system properly detected more than 50% of the pixels. Precision (Equation 4), recall
502 (Equation 5) and accuracy (Equation 6), were used for reporting the accuracy of image
503 segmentation techniques. For pixel-wise comparison between the expected and the achieved
504 were used the Mean Absolute Error (MAE) (Equation 7), Mean Percentage Error (MPE)
505 (Equation 8) and Mean Average Precision (MAP) (Equation 9) were calculated.

506

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

507

$$Recall = \frac{TP}{TP + FN} \quad (5)$$

508

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

509

$$MAE = (1/N) * \sum |y_i - x_i| \quad (7)$$

510

511 Where N is the number of samples, and $|y_i - x_i|$ the error in absolute values.

512

$$MPE = \frac{1}{N} \sum_{i=1}^N (\hat{y}_i - y_i) \quad (8)$$

513

514 Where N is the number of samples, \hat{y}_i is the forecasting value, and y_i is actual load
515 value.

516

$$MAP = \frac{1}{n} \sum_{k=1}^{k=n} AP_k \quad (9)$$

517

518 Where n is equal to the number of classes and AP_k the average precision of the class k .

519

520 **Software and hardware**

521

522 The experiments were conducted on a system running Windows 11 Home 23H2. Data
523 preprocessing was performed using Python 3.11.3 with scikit-learn (1.2.2) library. The deep
524 learning models were implemented with TensorFlow (v2.15) and Keras (v2.15) libraries. Code
525 development was carried out using Jupyter Notebook (v6.5.4).

526 Experiments were conducted on a system equipped with an Intel Core i5-12400 CPU
527 (6 cores, 12 threads) clocked at 2.50 GHz. Deep learning experiments were accelerated using

528 Intel® UHD Graphics 730 memory. The system was equipped with 24 GB of DDR4 RAM.

529 Data storage and retrieval were facilitated by a 500 GB NVMe SSD.
