Abstract

In early 2024, explosive outbreaks of Oropouche virus (OROV) linked to a novel viral lineage were documented in the Brazilian Amazon. Here, we report the introduction of this emerging orthobunyavirus into Colombia and its co-circulation with another OROV lineage. This investigation highlights the complex arbovirus dynamics in South America.

Keywords

Oropouche, Colombia, reassortment, fever, sequencing, outbreak, Leticia, lineages, Amazon.

Oropouche virus (OROV) is a reemerging arbovirus belonging to the *Orthobunyavirus* genus, *orthobunyavirus oropoucheense* species, of the family *Peribunyaviridae*. The three single-stranded, negative-sense RNA segments (L: Large, M: Medium, S: Small) of the OROV genome allow reassortments (1). Besides acute fever, OROV can cause meningitis and encephalitis. While biting midges, *Culicoides paraensis*, are the main vector of OROV in urban cycles, different insect species are vectors in sylvatic cycles. Vertebrates, such as primates, small mammals, and possibly birds, serve as reservoir hosts (1,2).

OROV has spread rapidly in South America causing over 500,000 infections (2,3). Most OROV cases have occurred in the Brazilian Amazon, where explosive outbreaks affecting sometimes thousands of inhabitants, have been reported after OROV identification in Trinidad and Tobago in 1955 (2,4,5). In a study conducted by our group in 2019-2021 in Colombia, we found that OROV and dengue virus (DENV) were responsible for over 10 and 20% of acute febrile illness, respectively, at four sites (Cúcuta, Cali, Villavicencio, and Leticia). The phylogenetic analysis revealed two separate OROV introductions into Colombia from bordering Ecuador (Cúcuta, Cali, and Villavicencio) and Peru (Leticia) (6).

In early February 2024, the PAHO/WHO issued an epidemiological alert because of the dramatic increase in OROV cases in four Amazonian states of Brazil (7). Over 1000 confirmed cases by RT-qPCR have been reported in the state of Amazonas alone between 2023 and January 2024 (8). Brazilian authors recently shared in a pre-publication the sequence data of the OROV

causing this large-scale outbreak. After analyzing over 100 full-length genomes, they identified multiple reassortment events and concluded that this virus is a new lineage (OROV_{BR-2015-2023}) (9). In this work, we are reporting the first OROV cases in Colombia caused by this newly identified viral lineage, which is co-circulating with another previously characterized OROV lineage (6).

The Study

In early January 2024, health authorities noticed a slight increase in acute febrile cases in the Leticia municipality, Amazonas department of Colombia, which has over 53,000 inhabitants. One-hundred and seventeen individuals complaining of chills (94.6%), headache (87.2%), arthralgia (65%), myalgia (41%), diarrhea (34.2%), fatigue (33.3%), and rash (6%) were treated at the emergency room of the Leticia hospital over five weeks. While fever ($\geq 38.5^{\circ}\text{C}$) was confirmed at the doctor's office in >46% of patients, less than 3% presented respiratory symptoms. No hemorrhagic manifestations were present in the febrile patients, nor were severe illnesses or hospitalizations documented among the studied individuals. Cases were between 7 and 92- years -old. Sixty individuals were male, and fifty-seven were female. After obtaining the written consent from adults and children's parents (or legal guardians), serum samples were collected. The protocol for this study was approved by the ethics committee of the Corporacion de Investigaciones Biologicas (SC-6230-1).

Frozen serum samples were shipped by air over 1300 km to One Health Colombia, located in Medellin city. One Health Colombia is a center established between the Global Health Institute at the University of Wisconsin-Madison and the National University of Colombia-Medellin. Following the center guidelines at One Health Colombia (6), serum samples were tested for arboviruses (zika virus or ZIKV, mayaro virus or MAYV, chikungunya virus or

CHIKV, DENV, OROV), hepatitis B and C viruses, *Leptospira* spp., and *Plasmodium* spp. using published and Abbott (Illinois, US) protocols (see **Appendix** and references therein).

DENV genome was detected by ZCD (zika, chikungunya, dengue) Trioplex real-time RT-qPCR in eight samples, which were also DENV non-structural protein 1 positive (N=4) or anti-DENV IgM positive (N=3). The study population had a high anti-DENV IgG prevalence of 77.7% (N=117). All samples were negative for ZIKV, CHIKV, and MAYV RNA. Seven samples presented *Plasmodium* spp. DNA by qPCR, with five samples showing positivity for the *P. vivax* antigen. No samples were positive for hepatitis B virus surface Ag, anti-hepatitis C virus antibody, and *Leptospira* spp. DNA.

Using our recently designed OROV RT-qPCR assay (6), OROV RNA of L and M segments were detected in eight samples. Next, NGS sequencing was conducted using metagenomic and target enrichment approaches in these eight serum specimens, as described previously (6). Phylogenetic analysis using available OROV genomes and the sequences of the new Brazilian clade, OROV_{BR-2015-2023} (9), revealed its presence in two samples from Leticia, LET-2099 and LET-2102 (**Figure 1**). While the L and S segments each branch as paraphyletic clades basal to OROV_{PE/CO/EC-2008-2021}, its M segment is more closely related to OROV_{BR-2009-2018} sequences. Amino acid changes of this new lineage compared to ancestral viral strains indicated multiple mutations in L and M segments (**Appendix**). In addition, six samples were detected from the OROV_{PE-CO-EC/2008-2021} lineage recently reported as circulating in 2019-2021 in Colombia (6) (**Table**). OROV cases did not exhibit co-infections aside from clinical manifestations of acute undifferentiated fever (**Appendix**) and they had not traveled outside of the Leticia municipality and its surrounding areas in the previous two weeks (**Figure 2**). Six full-

length genomes of OROV analyzed in this work, including the two novel OROV, were deposited in the GenBank under accession numbers PP477303-PP477320.

Conclusions

In the present cross-sectional study, we are reporting for the first time the circulation in Colombia of OROV_{BR-2015-2023}, a novel orthobunyavirus that was very recently documented in Brazil (9). Thus, this is the first report of the newly identified lineage of OROV outside Brazil. Given the numerous mutations in RdRp and glycoproteins for OROV_{BR-2015-2023}, enhanced replication and immune evasion capabilities likely increase viral fitness and transmission. In addition, we detected in six patients the co-circulation of an OROV lineage identified previously by our group in Colombia (6).

The identification of co-circulating strains of OROV exemplifies the evolving nature of orthobunyaviruses and raises concerns about future reassortment events and the emergence of new lineages with more severe clinical phenotypes and enhanced vector competence. In an arbovirus hotspot such as Leticia, it is not known if cross-protective immunity will exist between these two OROV lineages. Previously, a reassortant OROV isolated from outbreaks in Iquitos, the largest city in the Peruvian Amazon, provided limited cross-protection against an OROV strain (10).

Leticia municipality, the southernmost region in Colombia (**Figure 2**), remains isolated from the rest of Colombia's road network, and thus travelers typically reach Leticia by air. The capital of the Colombian Amazonas department, Leticia city, is in Leticia municipality where the borders of Colombia, Brazil, and Peru converge, forming an area known as the Three Borders. Tabatinga city, in the Brazilian state of Amazonas, is located right across from Leticia city

forming a unique suburban area nearby the Peruvian city of Santa Rosa de Yavarí, which is on an island in the Amazon River (11). Due to the significant human mobility related to local businesses, it is very likely that the new OROV lineage is spreading rapidly in these borderlands. Furthermore, we believe that the novel OROV in Leticia came from either a nearby settlement or air travelers from the Brazilian Amazon, where persistent outbreaks are occurring.

Our One Health center has previously reported outbreaks of ZIKV (12), DENV (13), OROV (6), and more recently has detected yellow fever virus (unpub. data) and MAYV (14) in Colombia, which underscores the dynamic landscape of reemerging arboviruses in this region. The sustained transmission of established strains and the unpredictable reassortment events of OROV able to cause outbreaks as described here is yet another demonstration of the public health challenges of surveillance, prevention, and control of arbovirus reemergence in the Americas.

Acknowledgments

We would like to thank the clinical and laboratory staff of the health-care institutions from Leticia city (Hospital San Rafael de Leticia, and Fundación Clínica Leticia) for their participation in our study. We also thank the staff of One Health Colombia, particularly the laboratory personnel, for their support in this work. Juan P. Hernandez-Ortiz and Laura S. Perez-Restrepo express their gratitude to Fundación Fraternidad Medellín and Fundación Sofia Perez de Soto for their unwavering support for the One Health Ph.D. awards. We are grateful for the map of the Leticia municipality in the Amazon basin, Colombia, generated by Celeny Ortiz Restrepo from One Health Colombia. This research was supported by the Global Health Institute

of the University of Wisconsin-Madison, the National University of Colombia-Medellin, and the virus discovery research program of the Abbott Pandemic Defense Coalition (APDC).

Figure 1. Time-scaled Bayesian phylogeographic tree of Oropouche viruses from Colombia. Bayesian phylogenetic trees of L (left), M (center) and S (right) gene segments were estimated using Beast (Bayesian Markov-Chain Monte Carlo > 100,000,000 generations) and IQ-Tree in ModelFinder (ultrafast bootstrapping and 1,000 replicates). Best-fit model was selected according to Bayesian information criteria. Strict molecular clock model was used for L and S segments, while an uncorrelated relaxed molecular clock model was used for the M segment. The phylogeny branches are colored according to their descendant place of origin (figure key). Bayesian posterior values (≥ 0.8) are annotated at specific nodes of the trees. Sequences from this study were compared to reference sequences from other studies. Main clusters are denoted with the following reference labels: BR 2015-2023 cluster represents the recent outbreak of the new lineage of OROV in Brazil from 2015 to 2023; PE/CO/EC 2008-2021 cluster represents sequences from Colombia, Peru, and Ecuador from 2008 to 2021; and BR 2009-2018 cluster represents sequences from Brazil from 2009 to 2018. Viruses from this study are represented by red circles with Let as the abbreviation of Leticia.

Figure 2. Map of the Leticia municipality and the Three Borders (Colombia, Peru, and Brazil) in the Amazon basin, Colombia. The map shows where the eight cases of OROV reside in the Leticia municipality. Yellow dots indicate cases with the newly identified OROV_{BR-2015-2023}. Macedonia, Vereda Santa Sofia, Santa Rosa de Yavari, and Tabatinga correspond to indigenous communities or cities. Map generated using QGIS Version 3.36.0 RC (03/12/2024).
