Supplementary File

Plasma proteomic signatures for atherosclerotic cardiovascular disease in the UK Biobank cohort

Supplementary Methods

Study design and population

Prevalent atherosclerotic cardiovascular disease (ASCVD) was defined as the composite outcome of either transient ischemic attack (TIA), ischemic stroke, or coronary heart disease at or before the baseline visit. Incident ASCVD was defined as having any of these conditions after the baseline visit. We used the following ICD-10 codes within UK Biobank's First Occurrences data to record the prevalence or incidence of these conditions.

Condition	ICD-10 code
Transient ischemic attack	G45
Ischemic stroke	I63
	I21.0 – I21.9, I22.0-I22.9,
	I23.1-I23.6, I24.0-I24.9,
Coronary heart disease	I25.1-I25.9

Measurement of clinical variables and polygenic risk scores

Clinical variables used to compute the QRISK3 along with additional clinical variables included in least absolute selection and shrinkage (LASSO) regression models are listed below. Of note, the QRISK3 score uses family history of a heart attack in a first degree relative. As this information is not currently available within the UK Biobank's database, we included family history of any heart disease instead.

Variables	UKB field code
Clinical variables used for the QRISK3 clinical score	
Sex	31
Age at recruitment	21022
Self-reported ethnicity	21000
Weight	21002
Height	12144
Smoking status	20160, 3456
Townsend deprivation index	22189
Systolic blood pressure	4080
Total cholesterol to HDL ratio	30690, 30760
Family history of heart disease	20107, 20110, 20111
Past medical history of T1DM	30870
Past medical history of T2DM	30750
Past medical history of erectile dysfunction	132088
Past medical history of migraine	131052
Past medical history of rheumatoid arthritis	131848

Past medical history of hypertension	131286
Past medical history of chronic kidney disease	132032
Past medical history of severe mental illness	130874, 130892
Past medical history of systemic lupus erythematosus	131894
Past medical history of atrial fibrillation	131350
Use of blood pressure-lowering medications	20003
Use of atypical antipsychotics	20003
Use of steroid medications	20003
Additional clinical variables used	
Glycated hemoglobin	30750
Self-reported alcohol use	1558
Physical activity category	22040
Triglycerides	30870
LDL cholesterol	30780
Lp(a)	30790
Standard polygenic risk scores (PRS) used in all three subcohorts	
Standard PRS for age at menopause	26202
Standard PRS for age-related macular degeneration	26204
Standard PRS for age at Alzheimer's disease	26206
Standard PRS for asthma	26210
Standard PRS for atrial fibrillation	26212
Standard PRS for bipolar disorder	26214
Standard PRS for body mass index	26216
Standard PRS for bowel cancer	26218
Standard PRS for breast cancer	26220
Standard PRS for cardiovascular disease	26223
Standard PRS for celiac disease	26225
Standard PRS for coronary artery disease	26227
Standard PRS for Chron's disease	26229
Standard PRS for epithelial ovarian cancer	26232
Standard PRS for estimated bone mineral density t-score	26234
Standard PRS for glycated hemoglobin	26238
Standard PRS for height	26240
Standard PRS for high-density lipoprotein cholesterol	26242
Standard PRS for hypertension	26244
Standard PRS for intraocular pressure	26246
Standard PRS for ischemic stroke	26248
Standard PRS for low-density lipoprotein cholesterol	26250
Standard PRS for melanoma	26252

Standard PRS for multiple sclerosis	26254
Standard PRS for osteoporosis	26258
Standard PRS for Parkinson's disease	26260
Standard PRS for primary open angle glaucoma	26265
Standard PRS for prostate cancer	26267
Standard PRS for psoriasis	26269
Standard PRS for resting heart rate	21150
Standard PRS for rheumatoid arthritis	26273
Standard PRS for schizophrenia	26275
Standard PRS for systemic lupus erythematosus	26278
Standard PRS for total cholesterol	21151
Standard PRS for total triglyceride	21152
Standard PRS for type 1 diabetes	26283
Standard PRS for type 2 diabetes	26285
Standard PRS for ulcerative colitis	26287
Standard PRS for venous thromboembolic disease	26289

Footnote:

a: For self-reported ethnicity, individuals who identified as British, Irish, or any other White background were classified as White or not stated; those who identified as African or any other Black background were classified as Black African; those who identified as Indian were classified as Indian; those who identified as Pakistani were classified as Pakistani; those who identified as Bangladeshi were classified as Bangladeshi; those who identified as Asian or Asian British were identified as Other Asian; those who identified as having a mixed background were classified as Mixed; all other individuals were classified as Other ethnic group. b: For both systolic blood pressure, two measurements were taken through an automated reading a few moments part. These measurements were averaged together. We also included the standard deviation of these measurements as a variable for the QRISK3 score. c: Self-reported medication data was used to classify the use of several medications. Statin medication use was recorded if atorvastatin, rosuvastatin, simvastatin, fluvastatin, pravastatin, velastatin, or eptastatin werelisted. Corticosteroid medication use was recorded if prednisolone, betamethasone, cortisone, depo-medrone, dexamethasone, deflazacort, efcortesol, hydrocortisone, methylprednisolone, or triamcinolone was listed. Lastly, second-generation antipsychotic medication was recorded if amisulpride, aripiprazole, clozapine, lurasidone, olanzapine, paliperidone, quetiapine, risperidone, sertindole, or zotepine was listed. d: Physical activity was defined as the summed Metabolic Equivalent Task (MET) minutes per week score. Individuals with a MET score of >3,000 minutes per week were classified as having high physical activity, those with a MET score between 600-3,000 minutes per week were classified as having moderate physical activity, and those with a MET score of <600 minutes per week were classified as having low physical activity. e: The 36 standard polygenic risk scores (PRSs) listed were generated by the UK Biobank using external genome-wide association study data.

Statistical Analyses

Two-sample Mendelian randomization analysis: Cis-protein quantitative trait loci analysis

We performed genome-wide association studies (GWASs) for all 2,920 proteins in a cohort of 15,016 UK Biobank participants to identify *cis*-protein quantitative trait loci (cis-pQTLs). Prior to GWAS analysis, SNPs with a minor allele frequency (MAF) < 0.001 or an imputation quality score < 0.3 were filtered. Individual NPX values were inverse-rank normalized prior to GWAS analysis. The GWAS analyses were performed using the REGENIE software, adjusting for several covariates: age, age², sex, proteomic batch, UKB recruitment center, UKB genotype array, the time interval between blood sampling and measurement, and the first 20 genetic principal components¹. Cis-protein quantitative trait loci (cis-pQTLs) were defined as SNPs located within 1 Mb on either side of the protein-coding gene. We pruned SNPs based on linkage disequilibrium with a r² threshold of 0.01. We also adopted a significance threshold of 5 x 10⁻⁸ for defining genetic instruments.

<u>Two-sample Mendelian randomization analysis: Obtaining effect estimates for atherosclerotic</u> cardiovascular disease

To obtain effect estimates for ASCVD, we ran a GWAS analysis of ASCVD in a cohort of UK Biobank participants ($n_{cases} = 64,386 \& n_{controls} = 299,887$). To avoid sample overlap with the group in which cis-pQTLs were identified in, we excluded participants who underwent proteomic profiling. The GWAS analysis was performed with the REGENIE software, and was adjusted for age, sex, genotype batch, and the first 10 genetic principal components¹. We filtered SNPs with a MAF > 0.01, minor allele count (MAC) < 100, genotype missingness > 0.1, or a Hardy-Weinberg equilibrium p-value > 10^{-15} . Samples with more than 10% missingness were also filtered for quality control.

<u>Two-sample Mendelian randomization analysis: Calculating proportion of variance explained</u> and F-statistics

We calculated the proportion of phenotypic variance (q^2) , the total proportion of variance explained (R^2) , and the F statistic using previously established methods described by others^{2,3}.

$$q^2 = 2 \times MAF \times (1 - MAF) \times \beta^2$$

where q^2 is the proportion of phenotypic variance, MAF is the minor allele frequency, and β is the effect size for a given SNP.

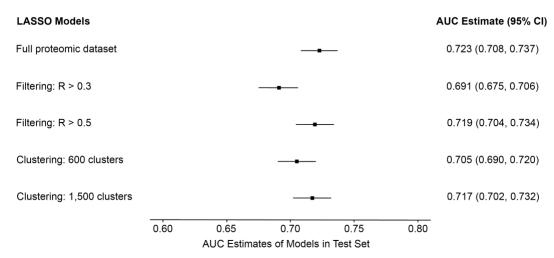

$$R^2 = \left(2~x~MAF~x~(1\text{-}MAF)~x~\beta^2\right)/~q^2$$

where R^2 is the total proportion of variance explained, MAF is the minor allele frequency, q^2 is the proportion of phenotypic variance, and β is the effect size for a given SNP.

$$F = R^2 * (N-1-k) / ((1-R^2) x k)$$

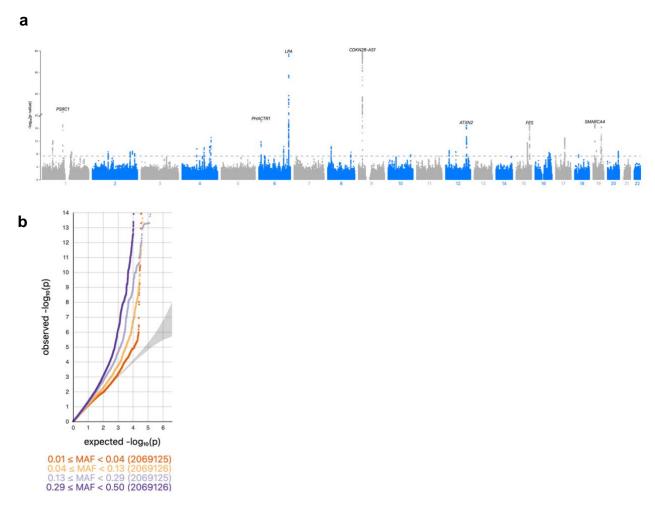

where F is the F statistic, R^2 is the total proportion of variance explained, N is the sample size, and k is the number of SNPs included in the instrument.

Supplementary Figure 1. Area under the curves (AUCs) using filtered and clustered proteomic datasets

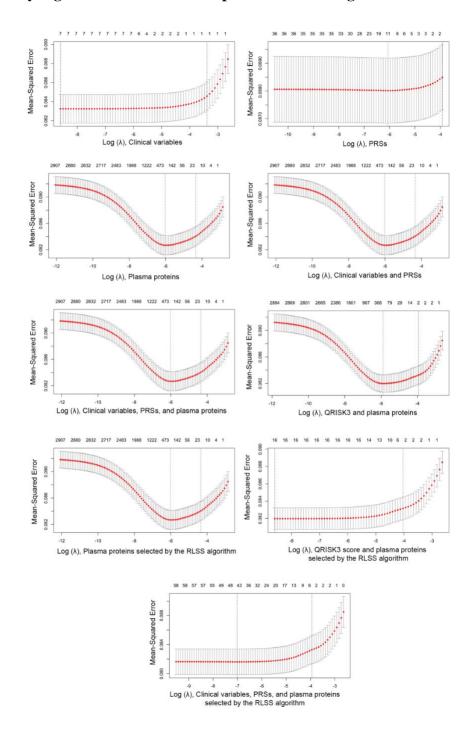

Footnote: Models performed in the training and test sets using filtered and clustered versions of the full proteomic dataset. **Abbreviations:** LASSO: least absolute shrinkage and selection operator, AUC: area under the curve, 95% CI: 95% confidence interval

Supplementary Figure 2a-b. Manhattan and Q-Q plots for genome-wide association studies of atherosclerotic cardiovascular disease in UKB participants of European ancestry

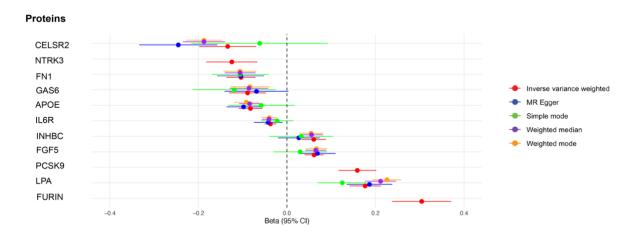

Footnote: (a) Manhattan plot of GWAS for atherosclerotic cardiovascular disease. (b) Q-Q plot of GWAS for atherosclerotic cardiovascular disease.

Supplementary Figure 3. Cross-validation plots of LASSO regression models

Footnote: Cross-validation plots of LASSO regression models in test data sets with atherosclerotic cardiovascular disease as the outcome of interest. Upper and lower standard deviation curves along the λ sequence (error bars) are shown. **Abbreviations:** PRSs: polygenic risk scores

Supplementary Figure 4. Potentially causal proteins for ASCVD

Footnote: Forest plot of potentially causal proteins for ASCVD based on Bonferroni-corrected threshold (p-value = 4.31×10^{-5}) using the inverse variance weighted method with results from other sensitivity analyses. Red denotes results from the inverse variance weighted method, blue from the MR-Egger method, green from the simple mode method, purple from the weighted median method, and orange from the weighted mode method. **Abbreviations:** 95% CI: 95% confidence interval
