

Supplementary Information:**Emotion regulation is robustly associated with depressive symptoms across the peripartum – data from a prospective Swedish national cohort study**

Franziska Weinmar, Emma Fransson, Birgit Derntl, and Alkistis Skalkidou

Results**Emotion regulation across the peripartum**

Pearson correlation analysis showed that the DERS-16 total score assessed between 16-25 weeks antepartum was strongly correlated with DERS-16 total score assessed between 17-25 weeks postpartum ($r(197) = .655, p < .001$; see *Supplementary Figure 1*). Further, we conducted paired samples t-test to assess differences in DERS-16 total score between the peripartum assessment periods. While DERS-16 total score was slightly higher in the postpartum ($Mean_{postpartum} = 32.45, SD_{postpartum} = 13.67$) compared to the antepartum assessment ($Mean_{antepartum} = 31.08, SD_{antepartum} = 12.44$), no significant difference in DERS-16 total score between the two timepoints was found ($t(198) = -1.78, p = .076$).

Differences in sample characteristics between peripartum depression trajectories

Group differences in sample characteristics between the peripartum depression trajectories were seen for *age* ($F(4,129) = 2.62, p = .038, \eta p^2 = .08$), with the early postpartum onset group being of marginally higher age than the late postpartum onset group ($p = .056$). All other trajectory groups did not differ in age at registration (all $ps > .231$). Furthermore, differences were found for *self-reported depression history* (Fisher's Exact Test, $p = .009$), with a higher distribution of depression history in the early postpartum onset followed by the persistent depression group. Also, groups differed on *SOC-13 total score* ($F(4,128) = 4.13, p = .004, \eta p^2 = .11$), with the persistent depression group having lower scores than the healthy group ($p = .003$); *RS-14* ($F(4,126) = 22.11, p < .001, \eta p^2 = .41$), with the late postpartum onset having lower scores than the healthy group ($p = .003$), and the persistent having lower scores than the healthy, antepartum only, and early postpartum onset depression groups (all $ps < .001$); *VPSQ total score* ($H = 31.61, p < .001$), with higher scores in the early and late postpartum onset than the healthy group (all $ps \leq .016$), and higher scores in the persistent than the healthy, antepartum only, and early postpartum onset groups (all $ps \leq .003$); *FOBS* ($H = 12.48, p = .014$), with higher scores for the early and late postpartum onset (all $ps \leq .05$) as well as higher scores for the persistent depression vs the healthy group ($p = .013$). No other

SUPPLEMENTARY INFORMATION

differences between the groups were found for the psychometric scales (all $ps \geq .053$). *Mode of delivery* differed between the trajectory groups (Fisher's Exact Test, $p = .008$) with the healthy group having more vaginal deliveries, the antepartum only and late postpartum onset group having more planned caesarean sections, and the early and late postpartum as well as the persistent having more acute caesarean sections. Lastly, *delivery experience* differed between groups ($H = 12.65$, $p = .013$) with the healthy reporting better delivery experience vs the late postpartum onset and persistent depression groups (all $ps \leq .035$) as well as the early postpartum onset reporting better delivery vs the persistent depression groups ($p = .048$). No further differences were found between the trajectory groups for delivery experience (all $ps > .098$).
