40

41 **Running title:** Coordinated cloud-based genome analysis for SARS-CoV-2

42

43 **Keywords:** COVID-19, SARS-CoV-2, public health genomics, bioinformatics

44

45 **Article Summary Line:** A cross-sectional study of SARS-CoV-2 sequencing demonstrates

46 that cloud-based sequencing analysis has the power to relieve bioinformatic bottlenecks,

47 and facilitate collaboration in pathogen surveillance to enhance pandemic preparedness.

48 **Abstract**

49 **Background**

50 Viral sequencing has made critical contributions to our understanding of and response to
51 the COVID-19 pandemic, but sequencing capacity and bioinformatic expertise remain
52 limited in many settings. This proof-of-principle study aimed to demonstrate the utility
53 of a cloud-based sequencing analysis pipeline, the Tiled Amplicon Pipeline (TAP), for
54 rapid and collaborative SARS-CoV-2 sequencing across seven globally distributed sites.

55

56 **Methods**

57 In this cross-sectional study from July to August 2022, seven sites submitted all SARS-
58 CoV-2 sequence data generated over a two-week period to our cloud platform. No patient
59 identifying information was uploaded, and human reads were removed prior to upload
60 to the cloud. Users could opt in to share sample information with collaborators via a
61 tagging system. The pipeline performed sequence assembly, lineage identification and
62 relatedness analysis.

63

64 **Results**

65 Seven sites contributed 5,432 sequences, of which 5,342 (98.3%) were from clinical
66 samples and 90 (1.7%) were controls. Of the clinical samples that were correctly
67 assembled, 3,439/4,179 (82.3%) had sufficient coverage for lineage assignment.
68 Omicron lineages dominated, with BA.5, BA.4 and BA.2 comprising the vast majority,
69 consistent with contemporary epidemiological observations at the time. Phylogenetic
70 analysis demonstrated low diversity within lineages, and genotypically identical or highly
71 similar sequences were recovered from globally disparate sites.

72

73 **Conclusions**

74 A cloud-based analysis platform like TAP addresses bioinformatic bottlenecks and
75 facilitates collaboration in pathogen surveillance, enhancing epidemic and pandemic
76 preparedness.

77 **Introduction**

78 Viral genome sequencing has proven pivotal to understanding the evolution of the SARS-
79 CoV-2 virus during the COVID-19 pandemic and in shaping the public health response.
80 International genomic surveillance and data sharing initiatives have together made it
81 possible to track the emergence of variants globally [1], to demonstrate the impact of
82 travel restrictions on viral dynamics across continents [2] or within countries [3, 4], and
83 to identify transmission routes within hospitals [5]. Successive waves of infection driven
84 by new variants showed that rapidly detecting new lineages is critical for understanding
85 disease epidemiology and guiding subsequent public health responses [6], as well as
86 informing the development of vaccines and therapeutics such as neutralising antibodies
87 [7-9].

88
89 However, the pandemic also highlighted marked global variability in sequencing capacity
90 and cost [10], with much of the SARS-CoV-2 sequencing undertaken at centralised
91 reference laboratories [11]. Several important challenges remain in expanding genomic
92 surveillance, including access to sequencing technology, availability of bioinformatic
93 expertise, and interpretability of results generated using a plethora of different wet lab
94 and bioinformatics protocols [12-14]. There is a need for accessible genomic surveillance
95 infrastructure that can be used by researchers and clinicians from any location, to deliver
96 an up-to-date global perspective of viral evolution.

97
98 One solution to both the shortage of bioinformatic expertise and the lack of global
99 interpretability of results is web-accessible analysis infrastructure [15]. The Global
100 Pathogen Analysis Service (GPAS) was rapidly set up in 2021 in response to the COVID-
101 19 pandemic by the University of Oxford as a cloud-based, globally accessible web

102 platform. GPAS provided fast and secure access to a comprehensive SARS-CoV-2 genomic
103 analysis pipeline, delivering genome assembly, variant calling and lineage classification
104 from raw sequence data. Users retained control of their data but could opt in to share
105 their data to facilitate comparisons in a wider context, empowering laboratories to
106 control their own analysis. GPAS was validated to UKAS ISO 15189:2012 standards in a
107 UK tertiary hospital clinical microbiology laboratory, and was commissioned by the UK
108 Health Security Agency for over a year to support Pillar 1 national surveillance and
109 various clinical trials. GPAS provided proof-of-principle that standard microbiology
110 laboratories without bioinformatics expertise can generate outputs for local surveillance
111 and automatically submit sequences to public repositories.

112

113 In 2024, GPAS was upgraded as the Tiled Amplicon Pipeline (TAP) with major
114 enhancements to several software components. Since January 2025 TAP has been
115 deployed as the SARS-CoV-2 pipeline on EIT Pathogena (version 1.2.0), a multi-pipeline
116 genomic pathogen analysis platform that is free of charge for users in low- and middle-
117 income countries and accessible in all settings with internet access [16]. This service
118 demonstrates the potential of cloud-based platforms to overcome barriers to
119 democratising effective genomic surveillance, making advanced genomic analysis
120 available to resource-limited laboratories.

121

122 In this paper, we report the results of a collaborative, cross-sectional SARS-CoV-2
123 sequencing study across seven globally distributed sites, which demonstrate the utility
124 of a cloud-based sequencing platform in providing a quality assured, rapid, and
125 integrated global snapshot of viral diversity. We further describe the components of the

126 pipeline and discuss its potential for rapid adaptation in response to future viral

127 pandemics.

128

129 **Methods**

130 **Pipeline development**

131 TAP was deployed to a cloud platform and controlled via a Command Line Interface (CLI)
132 tool. Full methodology is described in the Appendix (Supplementary Appendix A). At
133 upload, a universally unique identifier (UUID) is generated and assigned to each sample.
134 The mapping between the UUID and the user's sample identifier is downloaded and only
135 held by the user, and FASTQ header lines are also truncated, ensuring that no potentially
136 personally identifiable information is transmitted to the cloud platform. Tight access
137 control to data applies within TAP, and by default data is not shared with other users
138 unless explicitly authorised by the data owners.

139
140 Following FASTQ file upload to the cloud, processing commences automatically with no
141 further user input required. Any reads mapping to the human genome are first removed
142 [17], reducing the risk of any human reads being retained. Genome assembly is
143 performed by an amplicon-aware genome assembly tool Viridian v1.3.1 [18], which
144 scaffolds per-amplicon *de novo* assemblies into a single whole genome consensus
145 assembly in FASTA format. Viridian was configured to use the SARS-CoV-2 reference
146 genome Wuhan-Hu-1 (MN908947.3) for assembly and variant calling [19], and a library
147 of seven amplicon primer schemes (AmpliSeq v1; ARTIC versions 3, 4.1, 5.3.2 (400), 5.2.0
148 (1200); Midnight 1200; VarSkip v1a-2b). When a primer scheme is not specified by the
149 user, Viridan can automatically infer the most likely primer scheme from within its
150 library.

151
152 After assembly, amino acid mutations are identified using Nextclade [20], and Pango
153 lineages are assigned with Pangolin version 4.3.1 [21]. Aligned sequences are compared

154 using a novel algorithm, FindNeighbour5, which identifies single nucleotide variant
155 (SNV) distances between sequences without conflicting variant calls (0 SNVs) as well as
156 those differing by one, two and three SNVs [22, 23]. The main outputs from the pipeline
157 are presented in an access-restricted user interface portal and downloadable as a
158 summary file containing the lineage assignment, a list of related samples (according to
159 permissions), and metrics of the genome assembly (e.g. coverage, mean depth, amplicon
160 dropouts, etc). Detailed intermediate files such as VCF or FASTA files are also available
161 for download.

162

163 **Pipeline validation**

164 GPAS was validated for both Illumina and Oxford Nanopore Technologies (ONT)
165 sequencing platforms in 2021, using various datasets including a ‘truth set’ of cultured
166 SARS-CoV-2 samples sequenced with multiple platforms and library preparations,
167 annotated with manually curated variant calls (described in further detail in [18] and
168 [24]), in addition to community samples collected in Northumbria, UK. Overall, GPAS
169 showed negligible adjusted false call rates (less than 1/100,000 nucleotides) with respect
170 to the ‘truth set’, and had high concordance (less than 1.9/1,000,000 discordant events)
171 with the ARTIC assembly pipeline in use at the time.

172

173 TAP was subsequently validated against the same ‘truth set’ of cultured SARS-CoV-2
174 samples, which achieved 100% concordance with expected Pango lineages using the
175 same Pangolin version. Concordance of TAP and GPAS was further compared using data
176 from the current study, which showed 99.4% concordance in lineage calls (using the
177 same Pangolin and Viridian versions), and nucleotide call discordance of 0.59/1,000,000

178 sites. Further details of the validation and comparison processes are described in
179 Supplementary Appendix B.

180

181 **Sample frame, sequencing, and upload**

182 Between July and August 2022, seven sequencing centres participated in a two-week
183 sequencing pilot across seven countries: Senegal; Chile; South Africa; New South Wales
184 (NSW), Australia; Vietnam; United Kingdom (UK); and Virginia, United States (USA).
185 Centres were either accredited clinical microbiology or public health laboratories. All
186 clinical samples in which SARS-CoV-2 was detected were eligible for inclusion and
187 underwent in-house genomic sequencing at participating sites, with no more than one
188 submission from an individual patient. Sequencing platform (either Illumina or ONT) and
189 primer schemes were chosen by participating sites, who followed their established
190 sequencing protocols.

191

192 Raw sequences were uploaded in FASTQ format to GPAS, the working name of the
193 pipeline at the time, along with limited associated metadata (sample name, instrument
194 platform, sample type [clinical or control], collection date, and country). Submitting sites
195 verified the run quality reports of each sequencing batch including a review of positive
196 and negative controls, and batches were passed or failed accordingly. All passed samples
197 were tagged to release them to the shared data pool for subsequent aggregate analysis;
198 explicit permission was given from all collaborators to configure data access controls
199 such that all submitters could access and view each other's sequences, metadata, and
200 analytical outputs. For this study, primer scheme information was not provided by the
201 user, and automatic detection of primer scheme was enabled. All sequences were

202 uploaded to the European Nucleotide Archive (project accession: PRJEB70597) at the
203 time of the study.

204

205 **Data analysis**

206 FASTQ files from the study were redownloaded from the ENA and run through EIT
207 Pathogena (version 1.2.0 pre-release) on 6th November 2024. A maximum likelihood
208 phylogeny of aligned sequences was constructed for the three largest Pango lineages in
209 the sample set (BA.5, BA.4 and BA.2) using IQTree version 2.3.6, assuming a general time
210 reversible nucleotide substitution model with gamma rate heterogeneity, and using the
211 consensus tree from 1000 ultrafast bootstrapping [25]. All other analyses were
212 conducted in RStudio version 2023.06.0+421.

213 **Results**

214 **Primer scheme detection**

215 5,432 sequences were shared across seven sites (Supplementary Table 1), with date of
216 collection ranging from April to July 2022. Of submitted samples, 90 (1.7%) were controls
217 and 5,342 (98.3%) were clinical samples. Primer schemes were successfully auto-
218 detected for 4,238/5,432 (78.0%) of samples, but were incorrectly inferred for all
219 1,194/5,432 (22.0%) samples from NSW, Australia which appropriately failed the
220 Viridian quality control threshold for assembly. Further investigation showed that these
221 samples were sequenced using a bespoke primer scheme that is not included in the
222 current Viridian library, and these samples were excluded from further analysis.

223

224 **Aggregate analysis of global genetic epidemiology**

225 Among the clinical samples included in the analysis, 3,751/4,179 (89.8%) were
226 assembled with at least 70% genome coverage (Table 1). 3,439/4,179 (82.3%) clinical
227 samples were assembled with sufficient coverage and post-assembly quality to be
228 assigned a lineage (Table 2). 3,412/3,439 (99.2%) were Omicron variants, with BA.5,
229 BA.4 and BA.2 being the most common. A small number of Delta variant sequences were
230 identified (0.4%, 15/3,439), all of which were collected prior to July 2022.

231

244

245 **Global mixing across multiple Omicron lineages**

246 For clinical samples collected between 1st June 2022 and 31st July 2022, the proportion

247 of samples assigned to the different Omicron sub-lineages varied substantially by study

248 site (Figure 1). Each of BA.2, BA.4 or BA.5 dominated (constituted >50% of samples from)

249 at least one site, while in Senegal no single lineage dominated, and BA.4 and BA.5 were
250 equally common in South Africa (44.3% and 46.9% respectively).
251

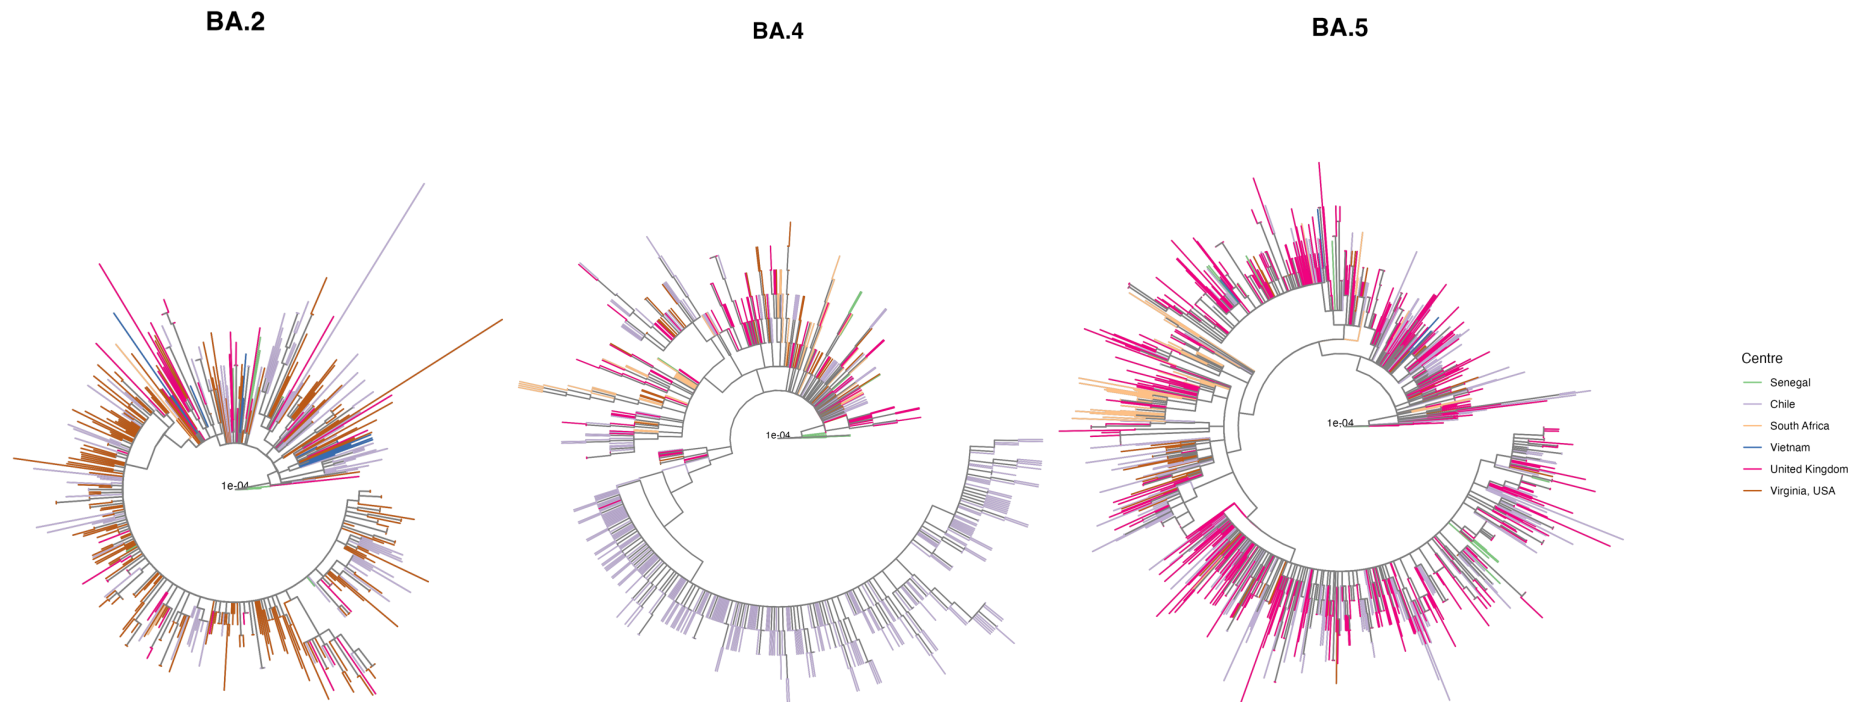

252

253

254 **Figure 1: Omicron sub-lineages by study site.** Proportion of samples assigned to Omicron sub-lineages
255 within each study site, where collection date was in June or July 2022.

256

257 Maximum likelihood phylogenies for each of the three most common lineages revealed
258 global mixing of Omicron lineages (Figure 2). There were no examples of sub-lineages
259 being completely geographically restricted to one site; one sub-lineage of BA.4 was found
260 predominantly in Chile, but an example of this sub-lineage was also identified in the
261 United Kingdom.

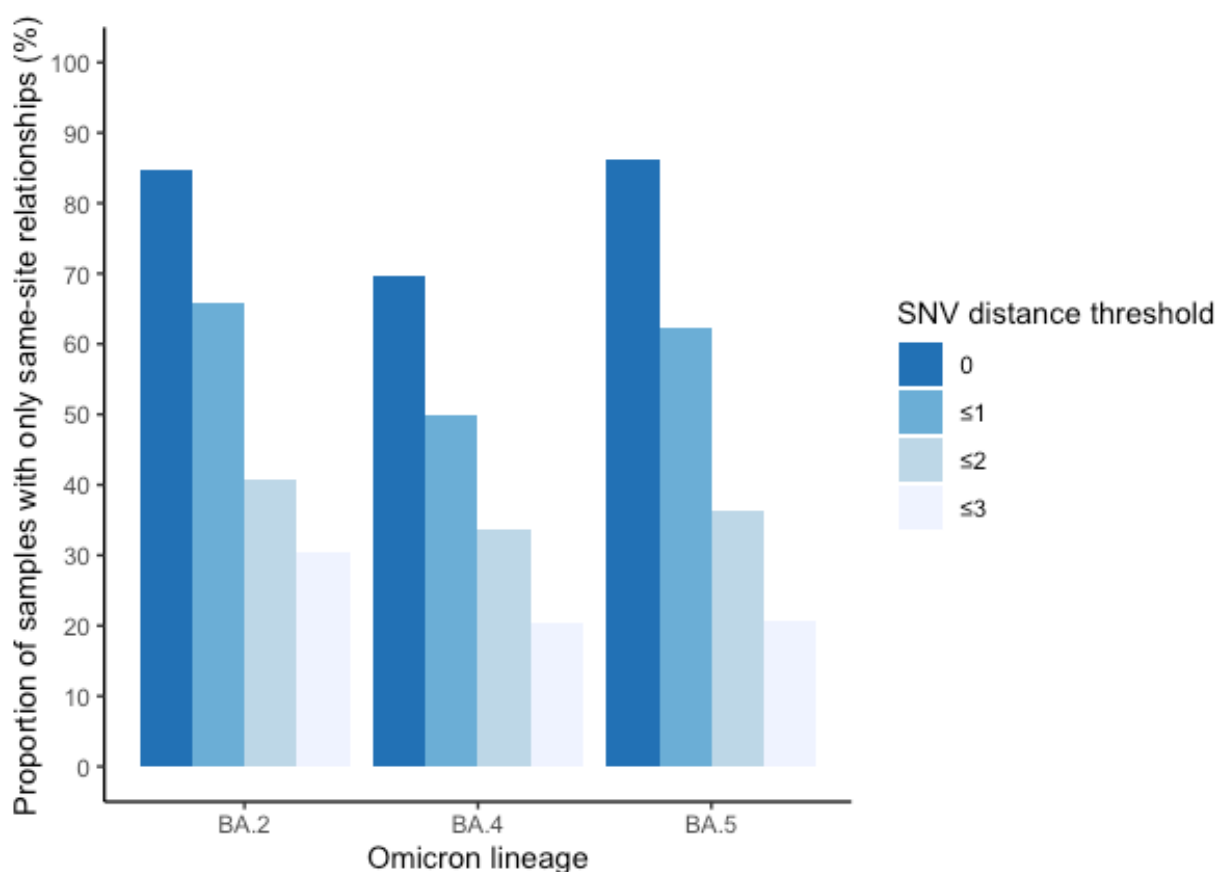

263

264 **Figure 2:** Maximum likelihood phylogeny of isolates from each major lineage (BA.2, BA.4, BA.5). Final branches are coloured according to the centre in which they

265 were sequenced.

266 For all three major lineages, there was evidence of genotypically identical (SNV = 0) and
267 highly related (SNV ≤ 3) samples being found in different study sites, with increasing
268 dispersal with higher SNV thresholds (Figure 3; Supplementary Table 2). The greatest
269 dispersal was seen in the BA.4 lineage: of 358 samples with another genotypically
270 identical sample, only 69.6% (249/358) were from the same site, with the rest
271 distributed across the remaining sites. In addition, only 10.3% (96/930) of BA.4 and
272 12.7% (173/1,361) of BA.5 samples did not have any related samples (SNV ≤ 3) in the
273 shared pool, in contrast to BA.2 samples where 51.8% (378/730) samples had a related
274 sample in the shared pool.

275

276

277 **Figure 3:** Percentage of unique samples for which all related samples were found only at the same site, at
278 each genotypic relatedness (SNV) threshold.

279

280 **Cloud processing time and performance**

281 At the time of the study, cloud processing performance on GPAS was measured by time
282 elapsed between upload and completion of analysis. Median cloud processing time per
283 sample was 30.6 minutes (IQR: 13.1 – 69.9); variability was observed, with several
284 batches from Australia, UK and USA taking longer than 1000 minutes (Supplementary
285 Figure 1). These were caused by either a data centre outage during an extreme heat event
286 in the UK, or as a result of a software update prematurely applied to the upload portal,
287 which was promptly resolved by improvements in the client side CLI software. Other data
288 upload issues were identified and addressed case-by-case, including metadata file
289 formatting errors, the availability of upload clients compatible with all required
290 operating systems, and user interface display errors preventing batch release.

291
292 In TAP, median cloud processing time per sample for a typical batch of 100 was 14.5
293 minutes (IQR: 13.8 – 15.0) for Illumina and 15.6 minutes (IQR: 15.2 – 16.7) for ONT; due
294 to parallelisation, processing a single batch of 100 samples was achievable in 19.7
295 minutes (Illumina) and 20.4 minutes (ONT) (Supplementary Figure 2). Processing all
296 5,432 samples took 766 minutes (12.7 hours). CPU time per sample is approximately 3
297 minutes (noting that this occurs in parallel, i.e. 2 CPUs working for 4 minutes would be
298 reported as 8 minutes CPU time by the workflow manager, despite only taking 4
299 minutes); majority of analysis time is associated with other pipeline activities including
300 network file transfers or reading data from disk into memory. Peak RAM usage for typical
301 use of the pipeline was approximately 5GB.

302 **Discussion**

303 This pilot study demonstrates the potential of globally synchronous data processing and
304 analysis in informing public health, through a unified protocol of genome assembly,
305 variant calling and relatedness analysis. The aggregated analysis from this study
306 conforms to contemporary observations of SARS-CoV-2 genetic epidemiology at the time
307 [26-28], and demonstrates cosmopolitan global mixing of Omicron lineages between
308 study sites. Even a BA.4 sub-lineage found almost exclusively in Chile was not completely
309 restricted to that site and could be identified in a geographically distant site (UK).
310 Similarly, between 15.3% to 30.4% of genotypically identical (SNV=0) sequences were
311 identified in different countries over the same two-month period. Such mixing of lineages
312 likely reflects the relaxation of travel restrictions in the participating sites at the time of
313 the study, and captures the rapid global dispersal of Omicron with successive selective
314 sweeps of new lineages over short time scales [29]. These observations highlight the
315 potential of a cloud-based sequencing pipeline in facilitating data sharing and generating
316 co-ordinated insights that could inform real-time decision-making.

317

318 While automatic primer scheme detection was used for this study, our results show the
319 limitation in this approach, with one centre using a custom scheme not contained in the
320 current Viridian primer scheme library. With viral evolution, it is inevitable that new
321 and/or modified primer schemes will continue to be developed to maintain sequencing
322 coverage of an evolving target genome. Viridian has the capability to accommodate
323 custom primer schemes when provided with a suitable scheme definition in browser
324 extensible data (BED) format. This capability will form the basis of future pipeline
325 iterations and will allow the pipeline to pivot in future to assemble other viruses beyond
326 SARS-CoV-2 that use tiled amplicon sequencing. In turn, this ability to rapidly adapt

327 existing infrastructure for emerging threats, rather than build bespoke solutions from
328 scratch each time, supports a proactive and ‘Always On’ approach to pandemic
329 preparedness [30].

330

331 Our study is limited by the opportunistic sampling frame used and is likely to be
332 geographically incomplete, with a preponderance for countries that have historically
333 contributed more to global sequencing efforts. Similarly, our study has the limitation of
334 lacking longitudinal data on how these findings changed over time. Despite these
335 shortcomings, we have demonstrated how even a simply structured sampling across time
336 and space is still well placed to rapidly identify replacement by new lineages. Such
337 limitations in sampling frame diversity and global disparity in sequencing volume were
338 reflected during the pandemic itself: sequencing efforts in high-income countries were
339 up to ten-fold higher than that achieved in low- and middle-income countries during the
340 first two years [11], and data was not collected evenly over the course of pandemic. Well
341 designed, suitably powered, and representative sampling is a key part of pandemic
342 preparedness planning, as exemplified by a cohort design in the UK [27].

343

344 The world is now better prepared to urgently initiate genomic pathogen surveillance. The
345 available sequencing platform capacity is much improved, and the achievements of global
346 data aggregation (as illustrated by INSDC, GISAID and Pathoplexus databases) have
347 alleviated a major obstacle to effective genomic surveillance and data sharing. In turn, the
348 integration of genomic data with disease manifestation and severity data would enable
349 the ready investigation of associations between genomic variation and clinical outcome
350 as suggested by others [31], and facilitate predictive modelling for anticipating the course
351 of future epidemics [32].

352

353 A remaining obstacle, especially in low-resource settings, is establishing local turnkey
354 bioinformatics to ensure standardised, quality-assured outputs that do not depend on in-
355 house bioinformatics expertise. In TAP, we have developed an exemplar of such a cloud-
356 based service, with simple ingestion of local sequence data and flexible privacy
357 protections for data sharing to facilitate local or international comparative analyses.
358 While factors such as internet bandwidth may limit real-world performance, TAP is
359 capable of rapid parallel data processing, with a run time of 15 minutes per sample and
360 20 minutes in total for a batch of 100 typical SARS-CoV-2 genomes. The EIT Pathogena
361 platform ensures sustainability of technical and infrastructural support to the pipeline
362 and is currently freely available to low- and middle-income countries, supporting long-
363 term use across research, clinical, or surveillance settings. Such a service, in turn,
364 contributes to the growing global landscape of genomic data sharing that will underpin
365 future pandemic preparedness.

366

367 **Conclusions**

368 The COVID-19 pandemic has demonstrated the multiple ways in which viral sequencing
369 can inform pandemic responses, but also the inequitable distribution of resources and
370 capabilities. A service such as TAP contributes to the democratisation of genomics,
371 enabling researchers and laboratories, regardless of their location or bioinformatics
372 expertise, to participate actively in global surveillance efforts. By providing accessible
373 and user-friendly tools for sequence assembly, lineage assignment, and data sharing, it
374 promotes inclusive collaboration, harmonises data, and ultimately enhances pandemic
375 preparedness.

376 **Author contributions**

377 Study conceptualisation: BCY, DWC

378 Study design: BCY, DWC

379 Software building and computational infrastructure: MB, BC, MH, ZI, PWF, JK, MLA, NS,
380 JS, RT, JW

381 Data collection: DA, NTA, JB, CCR, ACR, PMC, MMD, AD, NTD, LD, LVD, JE, KF, MG, JG, SG,
382 Hospital for Tropical Diseases SARS-CoV-2 testing team, NTTH, KJ, DK, TK, DNHM, AJM,
383 NMN, SO, HP, MRH, VS, NTTa, LVT, PNT, NMT, NTT_r, VDT, HRVD, AvG, NW

384 Data analysis: JT, BCY, BC, TEAP, PQ

385 Manuscript writing: JT, BCY, BC

386 Manuscript editing and review: all authors

387

388 **Funding statement**

389 GPAS is a non-profit organisation, and GPAS cloud infrastructure was supported by a
390 donation from Oracle Corporation. For this study, all GPAS services were offered free of
391 charge to all sites, and staff costs for the analysis team were met by the University of
392 Oxford, with support from the National Institute for Health Research (NIHR) Oxford
393 Biomedical Research Centre (BRC). TAP is deployed on the EIT Pathogena platform,
394 funded by the Ellison Institute of Technology Oxford. EIT Pathogena is free at the point of
395 use for users in low- and middle-income countries.

396

397 Sequencing activities for NICD are supported by a conditional grant from the South
398 African National Department of Health as part of the emergency COVID-19 response; a
399 cooperative agreement between the National Institute for Communicable Diseases of the
400 National Health Laboratory Service and the United States Centers for Disease Control and

401 Prevention (NU51IP000930); the South African Medical Research Council (SAMRC) with
402 funds received from the South African Department of Science and Innovation; the African
403 Society of Laboratory Medicine (ASLM) and Africa Centers for Disease Control and
404 Prevention through a sub-award from the Bill and Melinda Gates Foundation grant
405 number INV-018978; Africa PGI, the UK Foreign, Commonwealth and Development Office
406 and Wellcome (Grant no 221003/Z/20/Z); and the Department of Health and Social
407 Care's Fleming Fund using UK aid. NICD sequencing was also supported by The
408 Coronavirus Aid, Relief, and Economic Security Act (CARES ACT) through the Centers for
409 Disease Control and Prevention (CDC) and the COVID International Task Force (ITF)
410 funds through the CDC under the terms of a subcontract with the African Field
411 Epidemiology Network (AFENET) AF-NICD-001/2021.

412
413 Genomic surveillance conducted in Vietnam was supported by the Wellcome Trust
414 (222574/Z/21/Z). L.V.T. is supported by the Wellcome Trust of Great Britain
415 (204904/Z/16/Z and 226120/Z/22/Z).

416

417 **Ethical statement**

418 SARS-CoV-2 sequencing was performed for public health surveillance and ethical
419 approval for secondary analysis was not required. This determination was reviewed by
420 the University of Oxford Joint Research Office. No patient identifying information was
421 shared as part of this study. Sample identifiers remain with the submitter, and are never
422 kept on GPAS/TAP, or shared with other users. GPAS/TAP generates identifiers for each
423 sequence and writes a file linking anonymised ID to the submitted identifiers. Only the
424 user submitting sequence data has access to these records. The GPAS/TAP upload client
425 selects only SARS-CoV-2 sequence reads and discards all human sequences.

426

427 **Data availability**

428 Submitted sequencing reads (free from human reads) for all included samples are
429 available from European Nucleotide Archive study accession PRJEB70597.

430

431 **Conflicts of interest**

432 AvG and NW have received grant funding from Sanofi and The Bill and Melinda Gates
433 Foundation. PWF receives consultancy fees from the Ellison Institute of Technology,
434 Oxford. JT, DWC and TEAP receive funding from the Ellison Institute of Technology,
435 Oxford.
