SUPPLEMENTARY METHODS

Evaluation of the Assumptions of Linear Regression

We evaluated and confirmed that yearly data that were assessed in ordinary least squares regression, satisfied all assumptions of linear regression, including linearity, normality of residuals and homoscedasticity. In addition to visual assessment of plots, we employed the runs test assesses linearity based on randomness of the distribution of data points distributed around regression line. The test is based on the statistical assumption that if the data do not deviate significantly from linearity, data points are randomly distributed above and below the regression line. A "run" in the context of the test represent a series of consecutive points with either all positive or all negative residuals. If the number of points above the regression line are "N_{above}", and the number below the line are "N_{below}", the expected number of runs is: [(2 X N_{above} X N_{below})]+1. Fewer than expected number of runs is suggestive of deviation from deviation from linearity.

SUPPLEMENTARY TABLES

eTable 1: Covariates included in the risk-adjustment model for heart failure. The condition category (CC) codes represent combination of International Classification of Diseases (ICD) codes that are mapped to each condition. The codes required to map CC codes to ICD-9 and ICD-10 codes are available through the Centers for Medicare & Medicaid Services (Link:
