## Case definition and surveillance

### Case definition

In the first version of “Guideline on diagnosis and treatment of novel coronavirus infected pneumonia (NCIP)” issued by China CDC<sup>1</sup>, a suspected NCIP case was defined as pneumonia that fulfilled the clinical criteria (fever; radiographic evidence of pneumonia; low or normal white-cell count or low lymphocyte count; and no reduction in symptoms after antimicrobial treatment for 3 days following standard clinical guidelines) and had an epidemiologic link to the Huanan Seafood Wholesale Market in Wuhan or travel to Wuhan within 14 days before symptom onset. The definition of suspected case was updated in the second version issued on January 18, 2020 which deleted one of the clinical criteria (no reduction in symptoms after antimicrobial treatment for 3 days following standard clinical guidelines) to fasten the identification of cases and revised the epidemiological link as: a travel history to Wuhan or direct contact with patients from Wuhan who had fever or respiratory symptoms within 14 days of symptom onset or to be a potential case in a cluster<sup>1</sup>. The definition of suspected case was unchanged in the third version issued on January 22<sup>1</sup>. In the fourth version issued on January 27, the clinical criteria were loosened to meet any two of the three items in the previous two versions while the epidemiological link added one more link of association with laboratory confirmed case of COVID-19<sup>1</sup>. In the fifth version issued on February 4, clinically-diagnosed case defined as a suspected case with radiographic findings of pneumonia was added while only used in Hubei province<sup>2</sup>.

A laboratory confirmed case was defined as a suspected case with respiratory specimens tested positive for the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) by a genetic sequence that matches SARS-CoV-2 in the first version and added one more method of positive results by real-time reverse-transcription-polymerase-chain-reaction (RT-PCR) assay for SARS-CoV-2 in the second and the third version<sup>1</sup>. Laboratory-confirmed case in the fourth version added another option of positive results by RT-PCR from blood sample<sup>1</sup>. Confirmed case in the fifth version for Hubei province was defined as a clinically-diagnosed case or suspected case with laboratory results in the fourth version. These two types of confirmed cases were officially announced in Hubei province since February 12, 2020.

### Surveillance for identification of cases

Details of the surveillance for identification of cases has been described by Li et al.<sup>3</sup> and we briefly summarized as follows. The earliest cases were identified by the national “pneumonia of unknown etiology” surveillance system, which was defined as an illness without causative pathogen identified that fulfilled the following criteria: fever ( $\geq 38^{\circ}\text{C}$ ), radiographic evidence of pneumonia, low or normal white-cell count or low lymphocyte count, and no symptomatic improvement after antimicrobial treatment for 3-5 days following standard clinical guideline<sup>4</sup>. In response to a cluster of viral pneumonia of unknown etiology reported in Wuhan, Hubei province, a tailed surveillance protocol to identify potential cases were developed on January 3, 2020 with the same case definition in the first version of the above case definition<sup>5</sup>. Case definition was updated when a new version of “Guideline on diagnosis and treatment of novel coronavirus infected pneumonia (NCIP)” was issued. A national, provincial and municipal joint investigation team has been assembled to conduct field investigations and implement disease control and prevention measures. Detailed field investigation was conducted to collect information on dates of illness onset, exposure history during the 2 weeks before the illness onset, visit to clinical facilities, hospitalization and clinical outcomes using standardized questionnaire. Respiratory specimens were collected for laboratory test of real-time RT-PCR or genetic sequence. All suspected cases and laboratory-confirmed cases of COVID-19 were reported to the China CDC through a national surveillance system within 2 hours since NCIP was announced to be a notifiable disease in China on January 20<sup>5</sup>.

### Data source for aggregated data

Tab. S1 lists the sources used to extract individual case and aggregated data.

**Table S1. Data sources for extracting individual cases and daily aggregated data on COVID-19.**

Type of data sources	Main sources for extracting daily aggregated data
Type I: Websites of national, provincial, municipal and autonomous regional Health Commission	1. National Health Commission of the People’s Republic of China ( <a href="http://www.nhc.gov.cn">http://www.nhc.gov.cn</a> ) 2. Health Commission of Hubei Province ( <a href="http://wjw.hubei.gov.cn">http://wjw.hubei.gov.cn</a> ) 3. ### Completeness of the individual records

We assessed the completeness of all variables that included in this study (Tab. S2). The completeness of variables that related to cases' demographic (e.g., age and sex), time and location of case detected, exposures potentially related to COVID-19 were higher (range: 94.1-100%), while the time involving in estimates of key epidemiologic parameters of time to event distributions (i.e., the date of symptom onset, first healthcare consultation, and hospital admission) can be found in 45.5-93.4% of the COVID-19 cases.

**Table S2. Completeness assessment of variables used in the study.**

Variable	Outside Hubei (n=8,579)
Age	94.1%
Sex	97.3%
Location of case detection at city level	99.6%
Exposure history*	100%
Date of symptom onset	66.2%
Date of first healthcare consultation	47.2%
Date of hospital admission	45.5%
Date of official announcement	93.4%

\*We collected three types of potential exposure, including exposure to animals and seafood markets, or wild animals, or exposure to COVID-19 cases or patients with acute respiratory infection, or exposure to Wuhan/Hubei as we used in Table 1. According to the definition of suspected case that we described in page 1 of the Appendix, a suspected case should have an epidemiological link to Wuhan/Hubei (including travel history to Wuhan/Hubei or direct contact with patients from Wuhan/Hubei) or to be a potential case in a cluster. Thus, if no information about the travel history to Wuhan/Hubei of a confirmed case is reported in our individual records, we assume that the case locally acquired the infection. For exposure history, especially travel history to Wuhan/Hubei, it is 100% complete.

### Data consistence between our individual records and official line list

Considering more information on epidemiological investigation of the individual case were deeply revealed over time, we compared our real-time individual records that collected from official public source with official line list which released by Shandong Provincial Health Commission, Shenzhen Municipal Health Commission, and Hunan Provincial Health Commission since Jan 30, 2020. Individual records were then matched to the official line list according to the information on cases' demographic (i.e., age and sex), time and location of case detected. Individual records between our individual records and official line list were identified as the same individual if the records matched on cases' gender, age (less than 1-year-old), and official announcement (less than 1 day). Additionally, after observing the differences of the date of official announcement between municipal and provincial health commissions, a two-day lag of the date of official announcement was considered when comparing individual records in our study and official line list. Overall, a total of 299 cases in Hunan province, 302 cases in Shandong province and 312 cases in Shenzhen city were matched, respectively. The consistence of cases' demographic and the time involving in estimates of key epidemiologic parameters of time to event distributions are relatively higher (70.9-100.0%) between our individual records and official line list, while the consistence of the timing of case detected in Shandong province was relatively lower since the two-day lag of the date of official announcement was observed between provincial and municipal authorities. After cases matching and selecting, cases included in the official line list that could not be matched with our individual records were merged in our individual records, corresponding to 87 records in Shenzhen city (21.6% of total number of cases) and 17 records in Shandong province (3.3% of total number of cases) as of February 14, 2020.

**Table S3. Consistence between our individual records and official line list for the key variables.**

Variable	Consistence rate (%)		
	Hunan Province (n=299)	Shandong Province (n=302)	Shenzhen City (n=312)
Age			
Non-missing in our individual records and official data (% ,no./Total no.)	87.6 (262/299)	99.3 (300/302)	100 (312/312)
No difference	79.8 (209/262)	99.0 (297/300)	99.7 (311/312)
Difference between -1 and 1 year old	20.2 (53/262)	0.7 (2/300)	0.3 (1/312)
Missing in our individual records (% ,no./Total no.)	12.4 (37/299)	0.7 (2/302)	0 (0/312)
Sex			
Non-missing in our individual records and official data (% ,no./Total no.)	100 (299/299)	99.3 (300/302)	100 (312/312)
Missing in our individual records (% ,no./Total no.)	0 (0/299)	0 (0/302)	0 (0/312)

Date of symptom onset			
Non-missing in our individual records and official data (% ,no./Total no.)	70.9 (212/299)	54.0 (163/302)	96.2 (300/312)
No difference	90.1 (191/212)	93.9 (153/163)	99.7 (299/300)
Difference between -1 and 1 day	9.0 (19/212)	1.8 (3/163)	0.3 (1/300)
Missing in our individual records (% ,no./Total no.)	29.1 (87/299)	44.4 (134/302)	3.5 (11/312)
Date of first healthcare consultation			
Non-missing in our individual records and official data (% ,no./Total no.)	18.4 (55/299)	-	-
No difference	70.9 (39/55)	-	-
Difference between -1 and 1 day	20.0 (11/55)	-	-
Missing in our individual records (% ,no./Total no.)	75.9 (227/299)	-	-
Date of hospital admission			
Non-missing in our individual records and official data (% ,no./Total no.)	47.8 (143/299)	-	79.2 (247/312)
No difference	75.5 (108/143)	-	100 (247/247)
Difference between -1 and 1 day	20.3 (29/143)	-	-
Missing in our individual records (% ,no./Total no.)	50.8 (152/299)	-	20.8 (65/312)
Date of official announcement			
Non-missing in our individual records and official data (% ,no./Total no.)	-	98.0 (296/302)	-
No difference	-	1.0 (3/296)	-
Difference between -2 and 2 days	-	98.0 (290/296)	-
Missing in our individual records (% ,no./Total no.)	-	1.7 (5/302)	-

Note: reduced denominators indicate the difference above one day but less than two days

### Data representativeness

Tab. S4 shows a comparison between the number of confirmed cases by province (excluding Hubei) in our individual records and the total number of confirmed cases officially announced as of February 17, 2020. Figure S1 shows a comparison between the time series derived from our individual records and the officially announced cases for: i) all provinces of mainland China (except Hubei), and ii) seven of the most affected areas of mainland China (excluding Hubei Province). The estimation of the net reproduction number  $R_t$  was conducted on these seven locations and on the three additional locations that were validated against the official line list (see previous section).

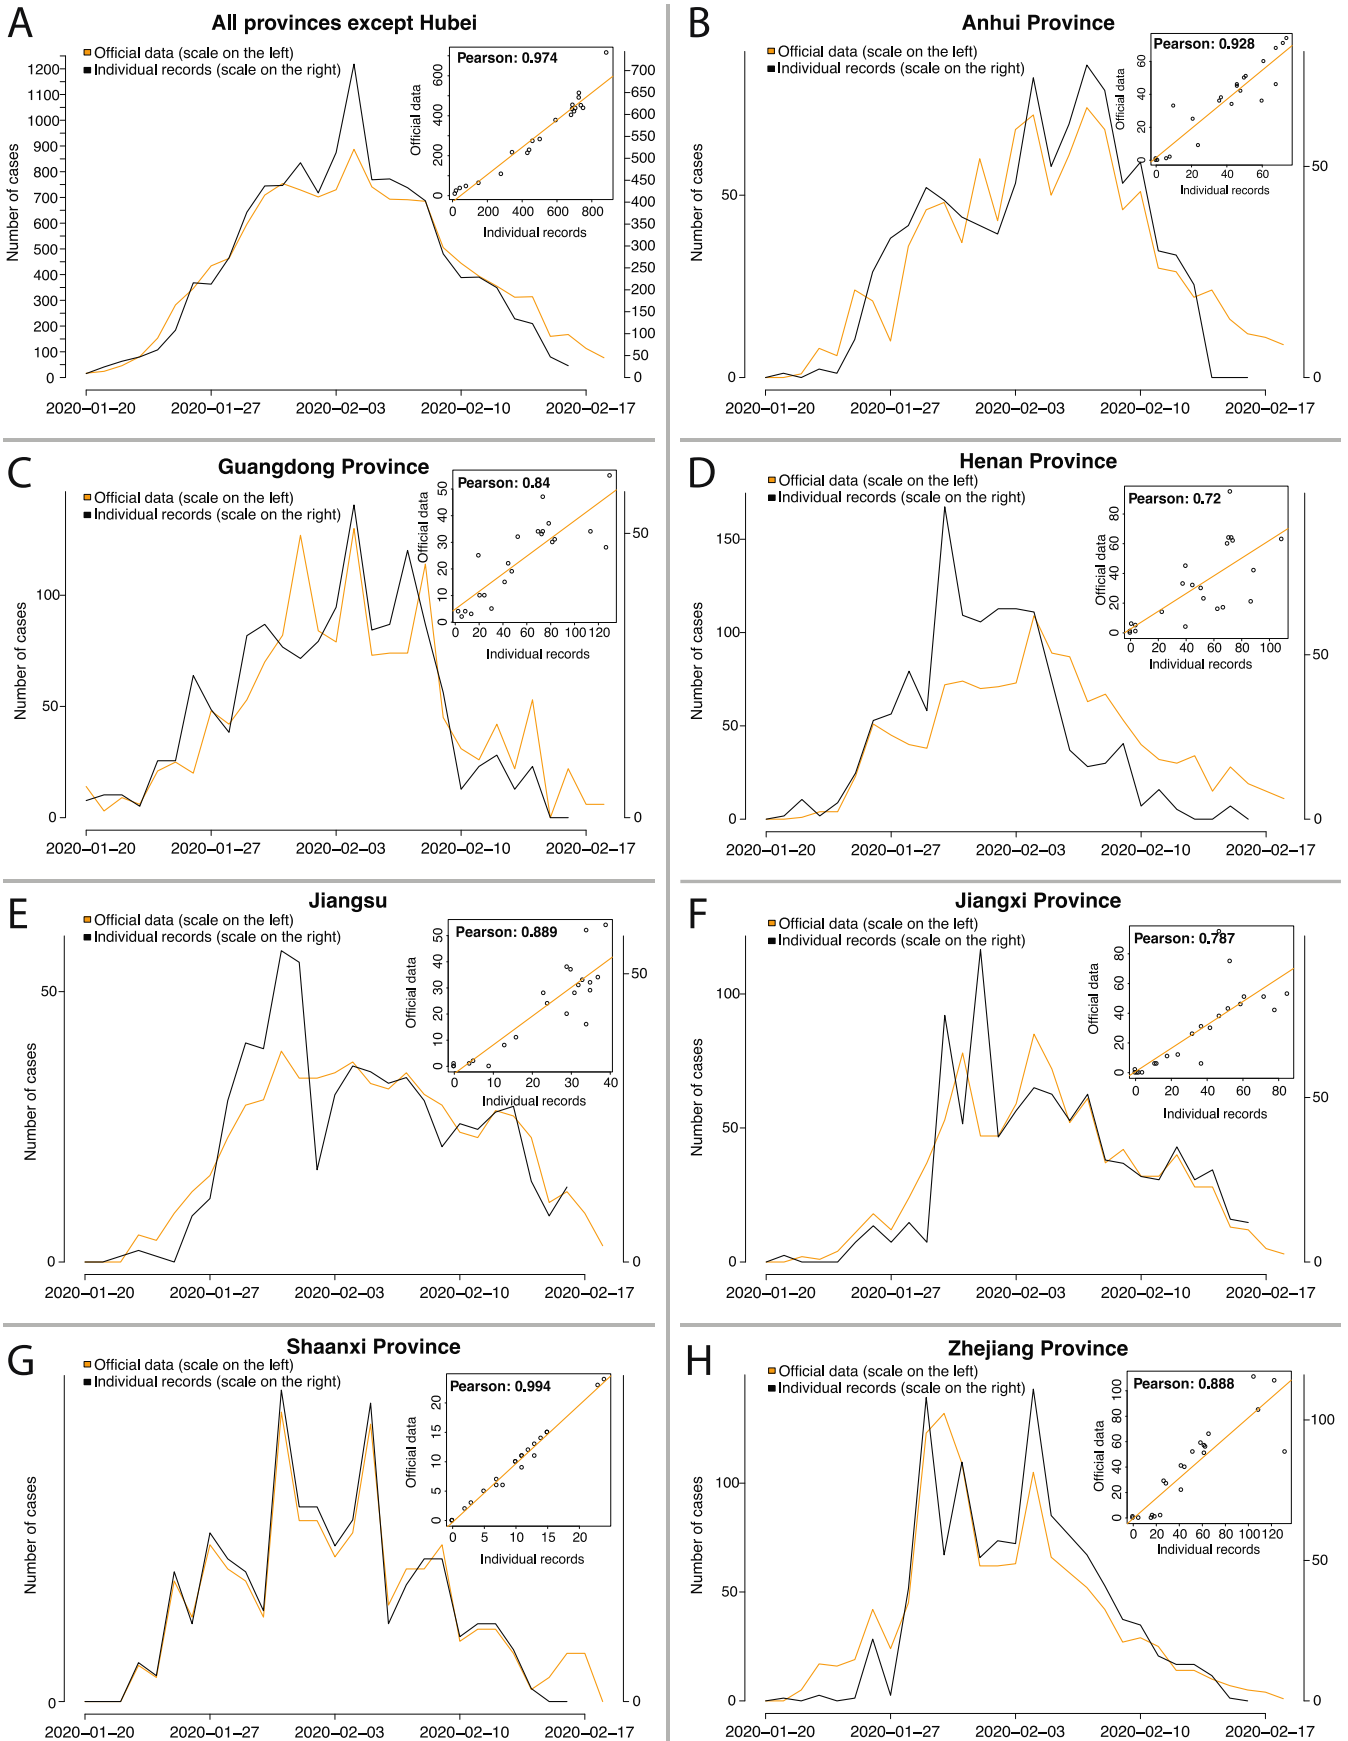

**Table. S4. Proportion of cases with individual data among total confirmed cases of COVID-19 by province/municipality in mainland China outside Hubei Province as of Feb 17, 2020. The 10 locations selected for the analysis on  $R_t$  are highlighted in bold.**

Province/ municipality	No. of cases with individual data	No. of total confirmed cases	Proportion (%)
Mainland China excluding Hubei	8,579	12,447	68.9
Province			
Guangdong	867	1,328	65.3
<b>Shenzhen city</b>	<b>401</b>	<b>416</b>	<b>96.4</b>
<b>Outside Shenzhen city</b>	<b>464</b>	<b>912</b>	<b>50.9</b>

**Figure. S1. A** Time series of confirmed cases (date of reporting) as resulting from our individual records and official announcements for all provinces of mainland China except Hubei. The inset shows a scatter plot of the two time series and the value of the Pearson's correlation coefficient. **B-H** Same as **A**, but for Anhui Province, Guangdong Province, Henan Province, Jiangsu Province, Jiangxi Province, Shaanxi Province, and Zhejiang Province, respectively.

### Age and sex distribution of cases

The age and sex distributions of COVID-19 cases disaggregated by epidemic period in Fig. S2.

**Figure. S2. Age and sex distribution of cases in provinces outside Hubei, stratified by epidemic period. A: Overall (n=7,936); B: Period 1 (n=3,820); C: Period 2 (n=2,270).**

### Key time to event intervals variable over time

We analyzed the individual records to obtain information about the following key time intervals:

- (1) Time from symptom onset to first healthcare consultation;
- (2) Time from symptom onset to hospital admission;
- (3) Time from first healthcare consultation to hospital admission;
- (4) Time from symptom onset to case announcement;

These time intervals may greatly depend on the behavior of the population, its response to the unfolding outbreak, and the local health care infrastructure. Therefore, we estimate provide different estimates for the two consider time periods of the epidemic.

We use maximum likelihood estimation to find the optimal parameters for the gamma, lognormal, and Weibull distributions. The fits of the three distributions are compared in terms of Akaike information criterion (AIC). The obtained results are reported in Tab. S5-S8.

**Table. S5. Estimation of the distribution of the time from symptom onset to first healthcare consultation.**

### Incubation period

The estimation of the incubation period is based on the information about the likely exposure of confirmed COVID-19 cases with asserted through forward contact tracing epidemiological link and no history of travel to Wuhan/Hubei. The exposure information is provided in the form of a time interval bounded by the date of the first and last possible exposure. The dataset contains the information on both the exposure date/dates and the date of symptom onset for 49 confirmed cases belonging to 37 clusters (a group of confirmed cases identified through forward contact tracing of an index case and linked through transmission events). We estimate the distribution of the exposure left-, right-, and interval-censored data by using maximum likelihood estimation and testing three distributions (Weibull, gamma, and lognormal)<sup>6</sup>. The goodness of fit is assessed in terms of Akaike information criterion (AIC). We found that the best fit is obtained by using a Lognormal distribution (see Tab. S9). The cumulative density function best fitting the data is shown in Fig. S3.

**Figure. S3. Cumulative density function of the lognormal distribution that best fits the data on the incubation period.**

**Table S9. Incubation period characteristics. Estimates based on the analysis of 37 clusters and 49 observations.**

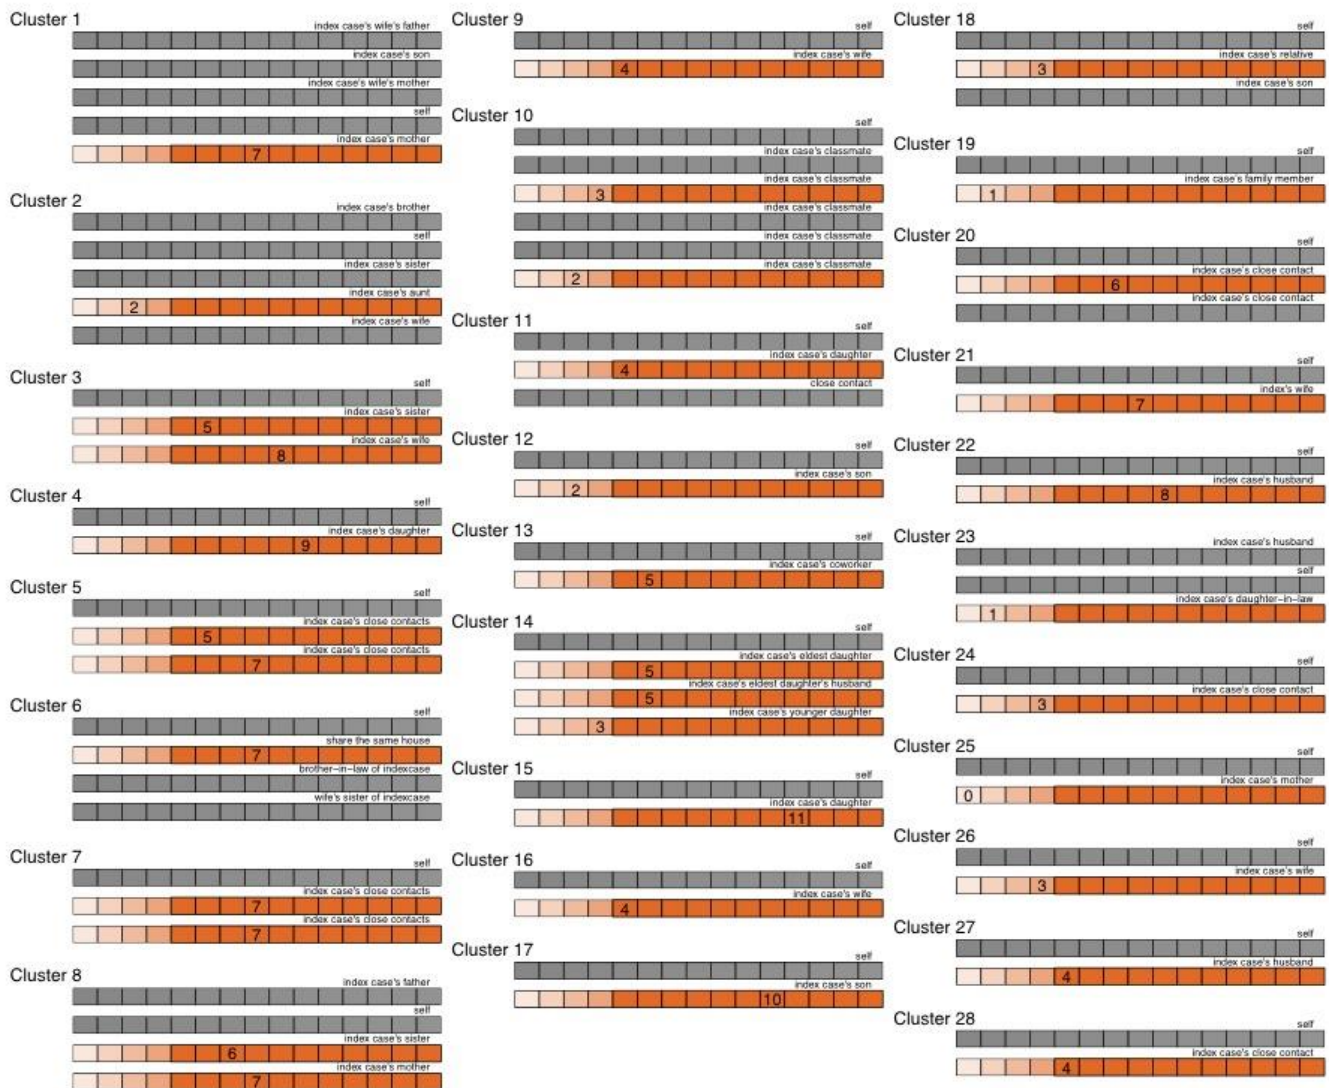

Distribution	Parameters mean (SD)	Mean (days)	95%CI (days)	AIC
<b>Gamma</b>	shape = 4.23 (1.28), rate = 0.81 (0.24)	5.2	1.5 - 11.3	104.9
<b>Weibull</b>	scale = 5.84 (0.56), shape = 2.03 (0.31)	5.2	1.0 – 10.9	106.8
<b>Lognormal</b>	meanlog = 1.54 (0.092), sdlog = 0.47 (0.072)	5.2	1.8 - 12.4	103.9

## Serial interval

We estimate the serial interval by applying maximum likelihood estimation to data on dates of symptom onsets between consecutive generations of cases within clusters with known epidemiological link and no travel history to Wuhan/Hubei. We focus on the transmission events that can be clearly identified, thus we omit cases when several infectors are possible. All the clusters used in this analysis are shown in Fig. S4.

As sensitivity analysis, we consider the possibility that, although with an identified epidemiological link, cases within a cluster that develop symptoms 1 up to 3 days after the date of symptom onset of the index case may have been infected by an unidentified infector. Therefore, we estimate four distributions of the serial interval by censoring raw cluster data.

The estimated serial intervals as well as the parameters of the best fitting gamma distributions are reported in Tab. S10. The fit of the gamma distribution to the empirical data is shown in Fig. S5.

**Figure S4. Time lag between the dates of symptom onset of cluster members and cluster index case. The relation of each cluster member with the index case is reported above each case. Numbers in boxes represent the time lag expressed in days. Cases represented in grey correspond to the index cases or to individuals for which it was not possible to establish a single infector through contact investigation.**

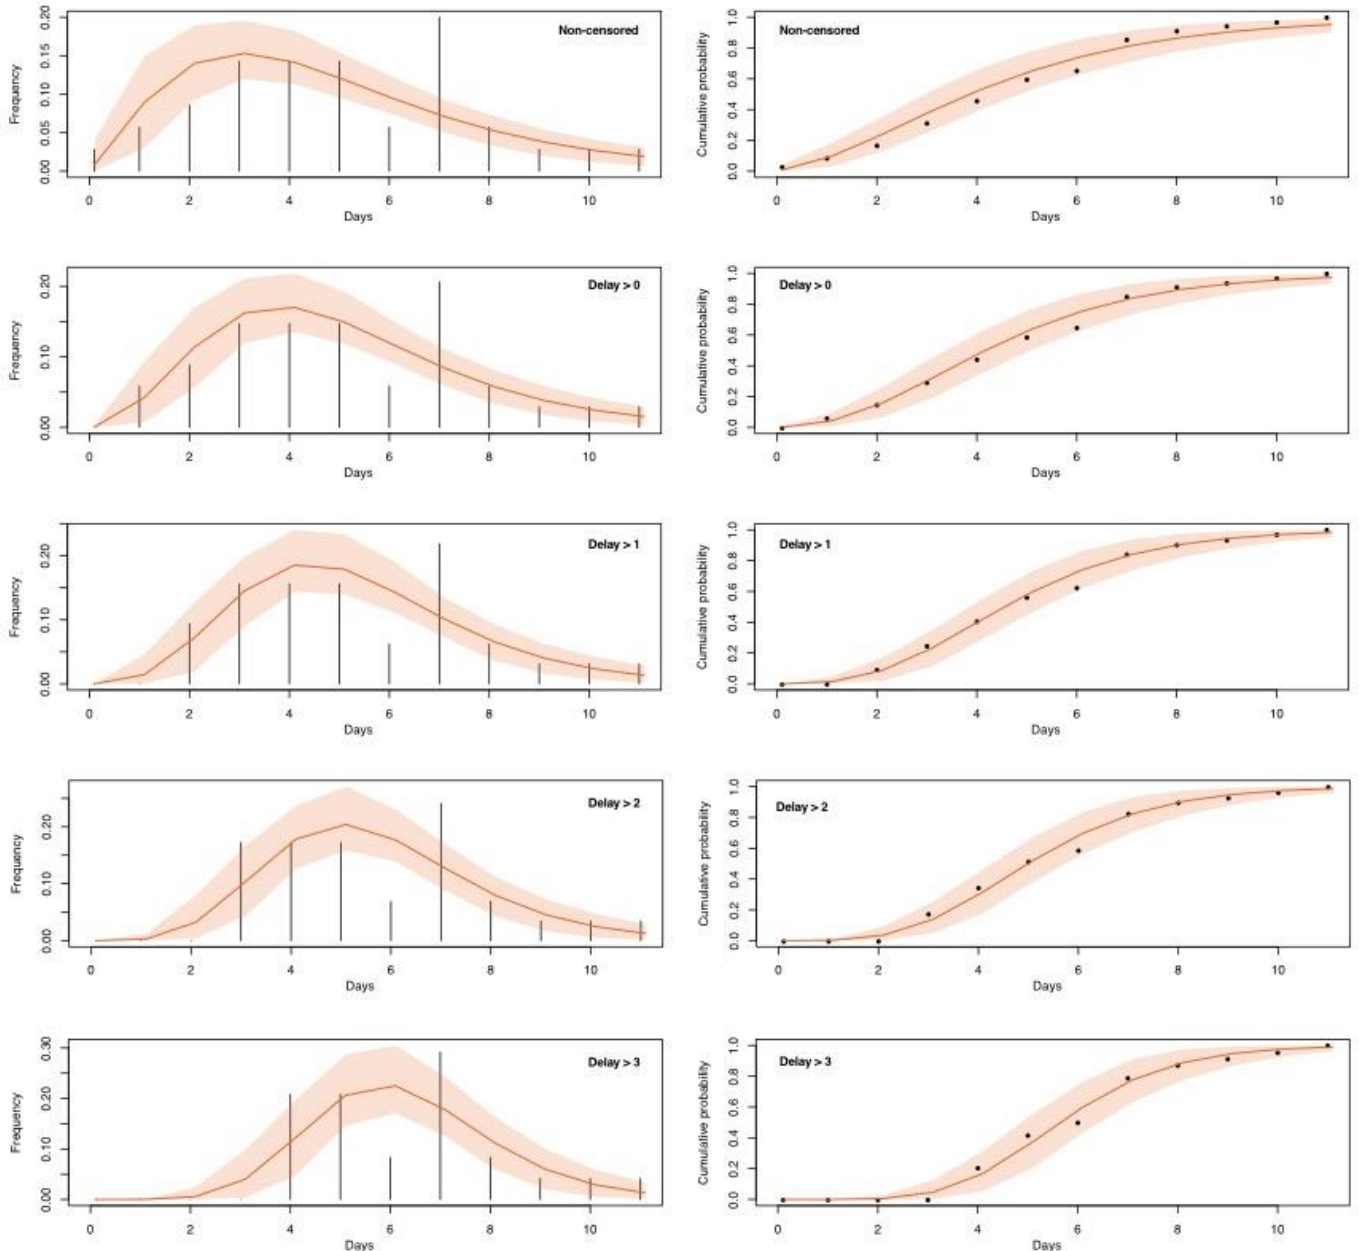

**Table. S10. Serial interval characteristics.**

Delay between symptom onset of index case and secondary cases	Number of clusters	Number of observations (excluding index cases)	Serial interval (95%CI), empirical data	Serial interval (95%CI), estimated from the fit of a gamma distribution	Parameters of the gamma distribution (shape, rate)
Non censored*	28	35	5.0 days (0.9-10.1)	5.0 days (0.8-13.0)	2.39, 0.48
>0 days#	27	34	5.1 days (1.0-10.2)	5.1 days (1.3-11.6)	3.63, 0.71
>1 day	25	32	5.4 days (2.0-10.2)	5.4 days (1.8-10.9)	5.18, 0.96
>2 days	23	29	5.8 days (3.0-10.3)	5.8 days (2.4-10.7)	7.28, 1.26
>3 days	19	24	6.3 days (4.0-10.4)	6.3 days (3.2-10.5)	11.49, 1.81

\* Considering all observations.

# Result presented in the main text.

## Reproduction number

The basic reproduction number  $R_0$  represents the average number of secondary cases generated by a primary infector in a fully susceptible population. In general terms, when  $R_0$  is larger than 1 the infection may spread in the population and the larger  $R_0$  the larger effort required to control the epidemic. Once the number of susceptible individuals decline, the transmission potential of the disease at a given time  $t$  is measured in terms of the net reproduction number  $R_t$ . The net reproduction number is useful to track the effectiveness of performed control measures and other factors affecting the spread of the epidemic (e.g., the behavioral response of the population) over time. As soon as  $R_t$  falls below 1, the epidemic starts to decline.

To estimate  $R_t$ , we adjusted the methodology presented in references<sup>7,8</sup> to account for the importation of cases. We assume that the daily number of new cases (date of symptom onset) with locally acquired infection  $L(t)$  can be approximated by a Poisson distribution according to the equation

$$L(t) \sim \text{Pois} \left( R(t) \sum_{s=1}^T \varphi(s) C(t-s) \right)$$

where

- $C(t)$ , with  $t$  from 0 to  $T$ , is daily number of new cases (date of symptom onset);
- $R(t)$  is the net reproduction number at time  $t$ ;
- $\varphi(s)$  is the distribution of the generation time (corresponding to the distribution of the serial interval) calculated at time  $s$ .

The likelihood  $\mathcal{L}$  of the observed time series of cases from day 1 to  $T$  conditional on  $C(0)$  is thus given by

$$\mathcal{L} = \prod_{t=1}^T P \left( L(t); R(t) \sum_{s=1}^T \varphi(s) C(t-s) \right)$$

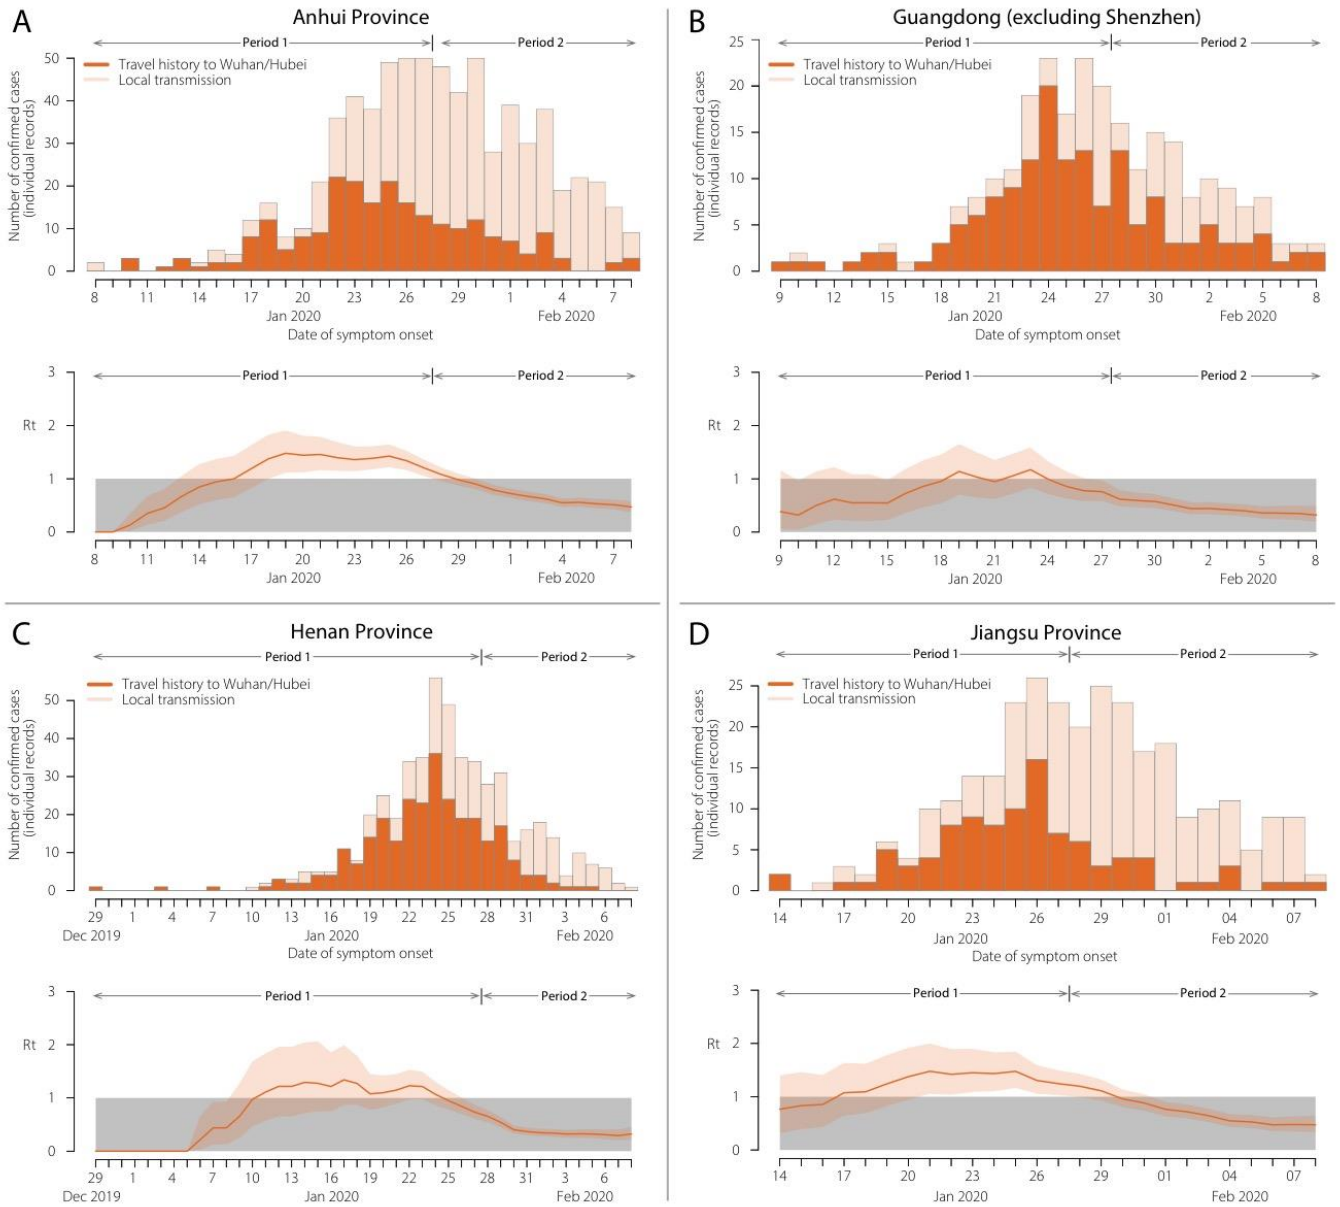

where  $P(k; \lambda)$  is the probability mass function of a Poisson distribution (i.e., the probability of observing  $k$  events if these events occur with rate  $\lambda$ ).

We then use Metropolis-Hastings MCMC sampling to estimate the posterior distribution of  $R(t)$ .

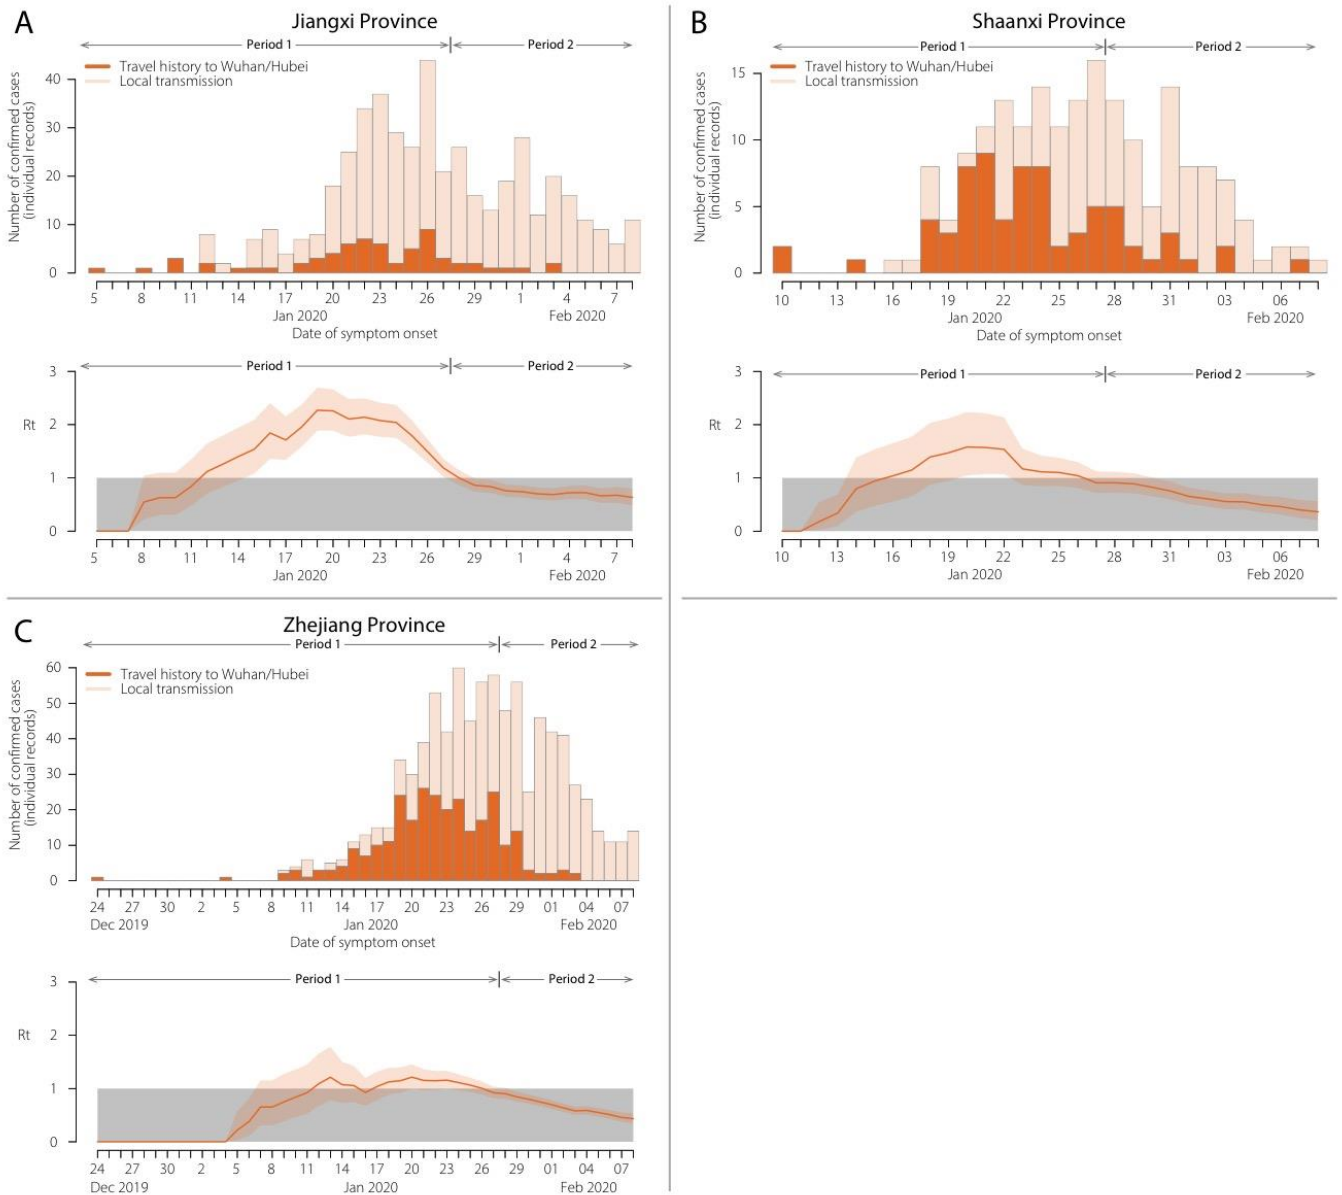

It should be noted that, when estimating  $R(t)$  we exclude data the last 9 days of the dataset to deal with the possible incompleteness of the dataset in the most recent dates due to reporting delays. The choice of 9 days is motivated by the fact that in the period from January 28 to February 17, we estimate the 90<sup>th</sup> percentile of the distribution of the time from onset to announcement in mainland China outside Hubei Province to be 9.0 days. We tested the robustness of this method by artificially right censoring all the data reported after January 28 and comparing the resulting estimates of  $R(t)$  with those obtained by using the dataset up to February 17.

It is important to mention that the developed method to estimate  $R(t)$  does not take into consideration the possibility that an imported case may have already started to transmit the infection during her/his travel. Although difficult to test, we feel that this is a limitation will have a negligible impact on the obtained estimates.

In the main text, we provided estimates of  $R(t)$  for three locations where we have validated our individual records against the full official line list compiled by the respective local health authorities. Here, we selected seven additional locations among the most affected provinces of mainland China (excluding Hubei Province) for which we have a representative sample (see Tab. S4 and Fig. S1). For these seven locations, the temporal series of confirmed COVID-19 cases and the estimated net reproduction number are shown in Fig. S6 and S7. The epidemic follows highly different patterns in the different provinces ranging from situations mostly characterized by the importation of cases and limited local transmission (e.g., Henan Province) to situations characterized by prolonged sustained local transmission reaching values as high as 3 (e.g., Jiangxi Province).

**Figure. S6. A Top: Daily number of new cases (date of symptom onset) in Anhui Province divided into cases with travel history to Wuhan/Hubei and local transmission. Bottom: Estimated net reproduction number ( $R_t$ ) over 4-day moving average by considering the estimated serial interval of mean 5.8 days (95%CI: 2.4-10.7). We excluded data after February 8, 2020 to account for the reporting delay – we estimated that during period 2 of the epidemic, the 90<sup>th</sup> percentile of the distribution of the time from onset to announcement in mainland China outside Hubei Province is 9.0 days. B Same as A, but for Guangdong Province (excluding Shenzhen). C Same as A, but for Henan Province. D Same as A, but for Jiangsu Province.**

**Figure. S7. A Top: Daily number of new cases (date of symptom onset) in Jiangxi Province divided into cases with travel history to Wuhan/Hubei and local transmission. Bottom: Estimated net reproduction number ( $R_t$ ) over 4-day moving average by considering the estimated serial interval of mean 5.8 days (95%CI: 2.4-10.7). We excluded data after February 8, 2020 to account for the reporting delay – we estimated that during period 2 of the epidemic, the 90<sup>th</sup> percentile of the distribution of the time from onset to announcement in mainland China outside Hubei Province is 9.0 days. B Same as A, but for Shaanxi. C Same as A, but for Zhejiang Province.**
