

Supplementary Information

Supplementary Table 01: Computational language analysis applied to dream reports. Raw data from participants that reported a dream before the COVID19 outbreak (identified as controls – Ctr) and after the announcement of the COVID19 pandemic by WHO (identified as subjects – Sub). Emotional analysis computed as the proportion of words with specific content; structural analysis computed as the number of nodes in the LCC or LSC (connected components of speech graphs) or the word count, and semantic analysis computed as average cosine between the words on dreams reports and the probe words identified on top. For dream reports from the pandemic period, all the measures were average per subject if the same participant reported more than one dream report at the follow-up. For more details, read Methods.
