Testing for nonlinear relationships: We test on the presence of a nonlinear relationship between the number of confirmed cases per million inhabitants and latitude. The coefficients of the added quadratic terms are insignificant at the 5% significance level, indicating that higher order polynomials are not adding value to our estimation.

5

Table S1. Results from OLS regressions of the number of COVID-19 cases per million inhabitants in a country on the country's latitude, quadratic terms of the latitude, and control variables.

	Cases per million inhabitants				
	(1) Coefficient 95% CI p value	(2) Coefficient 95% CI p value	(3) Coefficient 95% CI p value	(4) Coefficient 95% CI p value	(5) Coefficient 95% CI p value

N	117	117	117	117	117

Column 1 contains the bivariate specification of the regression of cases per million inhabitants on latitude. The other columns add control variables one by one. The results in this table refer to countries in which more than 100 cases were reported as of April 10, 2020.

“Latitude” is the absolute latitude of a country in degrees, “Latitude_squared” is the squared of the absolute latitude of a country in degrees, “air travel” refers to the number of air passengers per capita in a country, “distance to Wuhan” measures the distance of the capital city of a country to Wuhan in thousand kilometers, “vehicle concentration” is the number of registered vehicles per capita, “urbanization” is the percent of the population living in cities, “testing intensity” is the number of tests per confirmed case, “cell phone usage” refers to the number of cell phones per capita, and “income” refers to the purchasing-power adjusted per-capita gross domestic product in a country. Robust standard errors are used to account for heteroscedasticity.

Robustness test

We also perform robustness test by using robust estimation based on the mm-estimator that is less sensitive to outliers. The coefficient estimate for latitude is slightly higher than in case of the OLS regressions in Table 1, and the parameter estimate of latitude remain significant.

5 **Table S2.** Results from robust regressions based on the mm-estimator of the number of COVID-19 cases per million inhabitants in a country on the country’s latitude and control variables.

	Cases per million inhabitants
	Coefficient 95% CI p value
Latitude	0.029 (0.013 to 0.044) <0.001
Air travel	-0.005 (-0.054 to 0.044) 0.835
Distance to Wuhan	0.052 (-0.043 to 0.148) -0.283
Vehicle concentration	-0.431 (-1.536 to 0.673) 0.444
Urbanization	0.009 (-0.013 to 0.031) 0.433
Testing intensity	-0.027 (-0.037 to -0.018) <0.001
Cell phone usage	0.001 (-0.009 to 0.011) 0.831
Income	1.754 (1.188 to 2.319) <0.001
Constant	-13.703 (-18.054 to -9.353)
P value	<0.001
R ²	0.829
N	65

Column 1 contains the bivariate specification of the regression of cases per million inhabitants on latitude. The other columns add control variables one by one. The results in this table refer to countries in which more than 100 cases were reported as of April 10, 2020.

10 “Latitude” is the absolute latitude of a country in degrees, “air travel” refers to the number of air passengers per capita in a country, “distance to Wuhan” measures the distance of the capital city of a country to Wuhan in thousand kilometers, “vehicle concentration” is the number of registered vehicles per capita, “urbanization” is the percent of the population living in cities, “testing intensity” is the number of tests per confirmed case, “cell phone usage” refers to the number of cell phones per capita, and “income” refers to the purchasing-power adjusted per-capita gross domestic product in a country.
