Nord Ubangui - scenarios without gene drives

Nord Ubangui - scenarios with 300 gene drives released at year 0

Supplementary 4: Economic analysis

<u>Table S1</u> Average DALYs averted per year per one million population across all locations estimated from model's outputs in spatial simulation framework. Estimates of each scenario were compared with baseline scenario, which 50% ITNs and 19% ACT coverage were applied. For scenarios that included gene drives, only the estimates from scenarios that resulted in malaria elimination were included.

			Average DALYs averted per year per one million

Notes for Table S1:

1) NA: Not applicable

2) Green highlight: the scenario achieved malaria elimination

3) It is possible that the DALY averted results turned out to be negative figures in some scenarios since the combination of ITNs at 50% coverage and ACT at 19% coverage was applied in the baseline scenarios that were used as a comparator to reflect reality. For example, a 50% ITNs scenario means only ITNs at 50% coverage was applied as a single intervention in the scenario. Therefore, it is understandable that the lower efficacy of 50% ITNs alone could be observed once compared to the comparator in which the combination of 50% ITNs and 19% ACT was applied. Negative DALYs averted are in red texts.

4) WHO estimated the DALYs averted using null (do nothing) scenario as a comparator.

Note for Table S2: 1) NA: Not applicable

2) The scenarios that could achieve malaria elimination when adding gene drives were highlighted in green.

3) \$int: International Dollars

4) upper bound: upper bound price, lower bound: lower bound price

<u>Table S3</u> Incremental cost-effectiveness ratio in year 1-5 after applying intervention(s)

Keys for Table S3:

- ICER: Incremental cost-effectiveness ratio
- Negative: the incremental cost and the incremental effect are negative
- Dominated: the incremental cost is positive, and the incremental effect is negative
- Vector control strategies that could reach malaria elimination were highlighted in green.
- Incremental cost-effectiveness ratio (ICER) is defined as the incremental change in cost, divided by the incremental change in its effectiveness. The first, second, and third points of each expansion path were highlighted in red, orange, and yellow accordingly.
