Abstract

The knowledge on the deposition and retention of the viral particle of SARS-CoV-2 in the respiratory tract during the very initial intake from the ambient air is of prime importance to understand the infectious process and COVID-19 initial symptoms. To give some light on that, we propose to use a modified version of a widely tested lung deposition model developed by the ICRP, in the context of the ICRP Publication 66, that provides deposition patterns of microparticles in different lung compartments. In the model, we mimicked the “environmental decay” of the virus, determined by controlled experiments related to normal speeches, by the radionuclide ^{11}C that presents comparable decay rates. Our results confirm clinical observations on the high virus retentions observed in the extrathoracic region and the lesser fraction on the alveolar section (in the order of 5), which relevance is a subject to be investigated.

Keywords: SARS-CoV-2, COVID-19, respiratory tract, viral load, radionuclides, ICRP-66.

Supplementary Material

Model: C, Isotope: C-11

Observation: Carbon according with ICRP-67

Subject: Standard Worker (Nose Breather)

Intake: Inhalation, Single

Element: 1 (Series with 1 element(s))

Initial or Daily Activity: 1.00E+00 Bq

Inhalation: Respiratory Tract: ICRP-66

Compound: Type F

GI Tract Absorption Factor: F1 = 1.00E+00

AMAD (um): 5.00E+00
