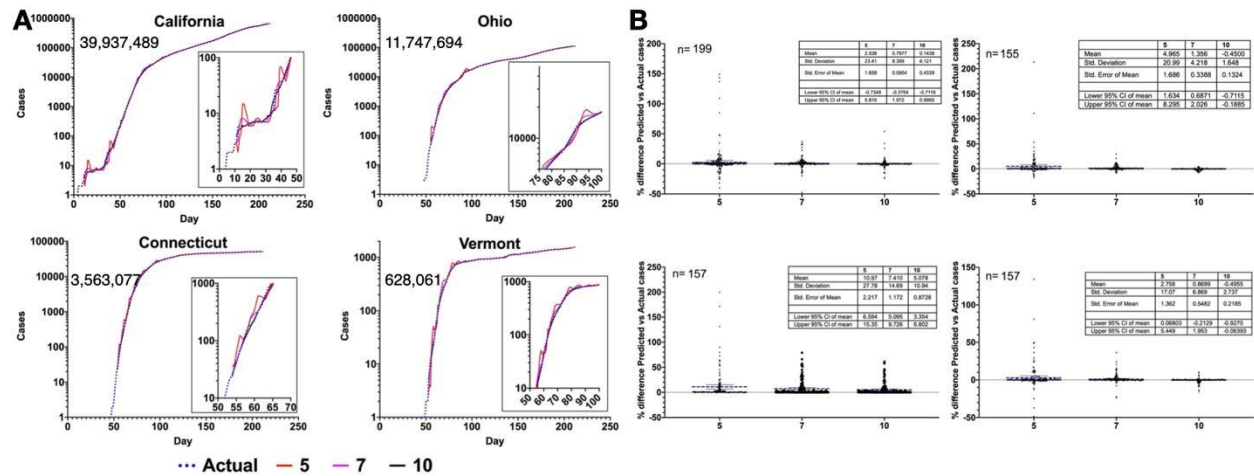

Figure S1: Sensitivity analysis of our short-term prediction using four states as an example over the course of the pandemic. A) Using historical data and our five, seven and ten day prediction algorithm the predictions are plotted for each curve 7 days into the future. The inset shows a zoomed in region to be able to distinguish the three prediction lines from the actual cases. The actual cases are shown in each graph as dotted blue line, while the predictions using 5 day

data (red), 7 day data (purple) and 10 day data (black). In each of the graphs the population of the state is given. B) Statistical analysis of our predictions during the course of the pandemic for each of these states. The graphs show for every data point by what percentage our prediction was inaccurate. Note that the mean error becomes smaller when more data points are used for the prediction. The number of data points over which a prediction was made is denoted in the upper left corner of each graph.
